

CS106L Lecture 5:

Streams

Fabio Ibanez, Jacob Roberts-Baca

Attendance

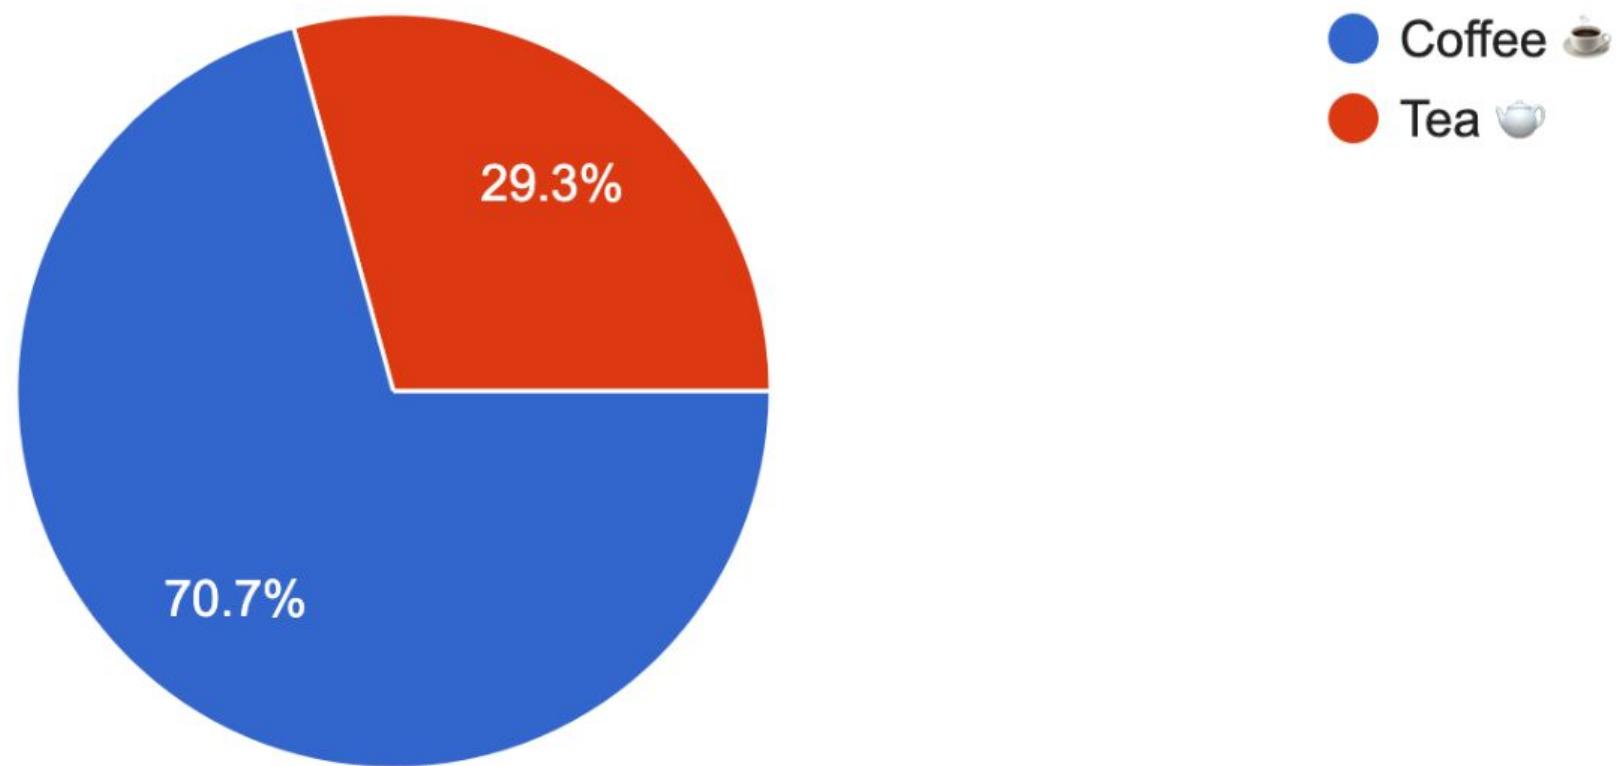

Interesting Stats

Coffee or Tea? (There is one right answer)

41 responses

Personally

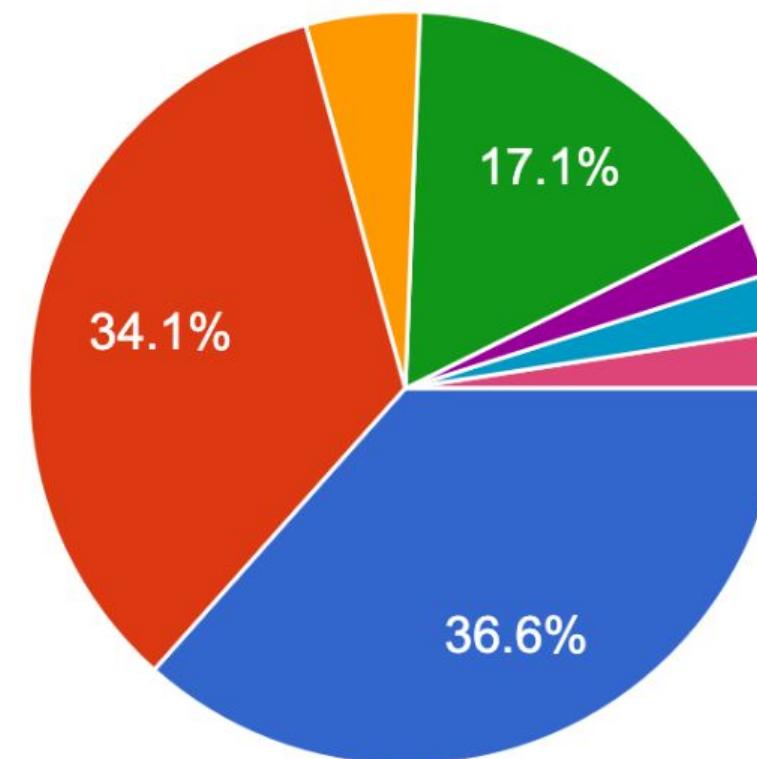

Interesting Stats

Which describes your current status?

41 responses

- Present and caffeinated!! ☕
- Here, but I would like caffeine 😔
- My cat is attending on my behalf 🐱
- Physically here, mentally in Hogwarts 🧙
- Here, but would like tea
-
- Physically here, not a fan of coffee OR tea, actually ate lunch beforehand

For the people in Hogwarts (or anyone)

This is a friendly reminder to let us know how to make this class better for you by submitting feedback using our anonymous feedback form [here](#). **We're interested in why your cat is attending on your behalf, or why you're in Hogwarts!**

I've even made a QR code for your convenience 😎 (the slides are up on the website):

Plan

1. Quick recap
2. What are streams??!!
3. `stringstreams`
4. `cout` and `cin`
5. Output streams
6. Input streams

A quick recap

1. Uniform Initialization

a. A *ubiquitous and safe* way of initializing things using {}

A quick recap

1. Uniform Initialization

- a. A *ubiquitous and safe* way of initializing things using {}

2. References

- a. A way of giving variables **aliases** and having multiple variables all refer to the **same memory**.

Plan

1. Quick recap
- 2. What are streams??!!**
3. stringstream
4. cout and cin
5. Output streams
6. Input streams

Why streams?

"Designing and implementing a general input/output facility for a programming language is notoriously difficult"

- *Bjarne Stroustrup*

So I did it

Streams

"~~Designing and implementing~~ a general input/output facility for a programming language is notoriously difficult C++"

- *a stream* :)

Streams

a general input/output facility for C++

Streams

a general input/output facility for C++

a general input/output(IO) abstraction for C++

Abstractions

Abstractions provide a consistent *interface*,
and in the case of streams the interface is for
reading and writing data!

A familiar stream!

```
std::cout << "Hello, World" << std::endl;
```

A familiar stream!

```
std::cout << "Hello, World" << std::endl;
```

This is a stream

A familiar stream!

```
std::cout << "Hello, World" << std::endl;
```

This is a stream

The **std::cout** stream is an instance of **std::ostream** which represents the standard output stream!

std::cout

```
std::cout << "Hello, World" << std::endl;
```

std::cout

“Hello, World”

std::cout

```
std::cout << "Hello, World" << std::endl;
```

std::cout

“Hello, World”

**But how do we go from external
source to program?**

An Input Stream

How do you read a **double** from your console?

std::cin is the console **input stream**!

The **std::cin** stream is an **instance** of **std::istream** which represents the standard input stream!

```
void verifyPi()
{
    double pi;
    std::cin >> pi;
    /// verify the value of pi!
    std::cout << pi / 2 << '\n';
}
```

std::cin

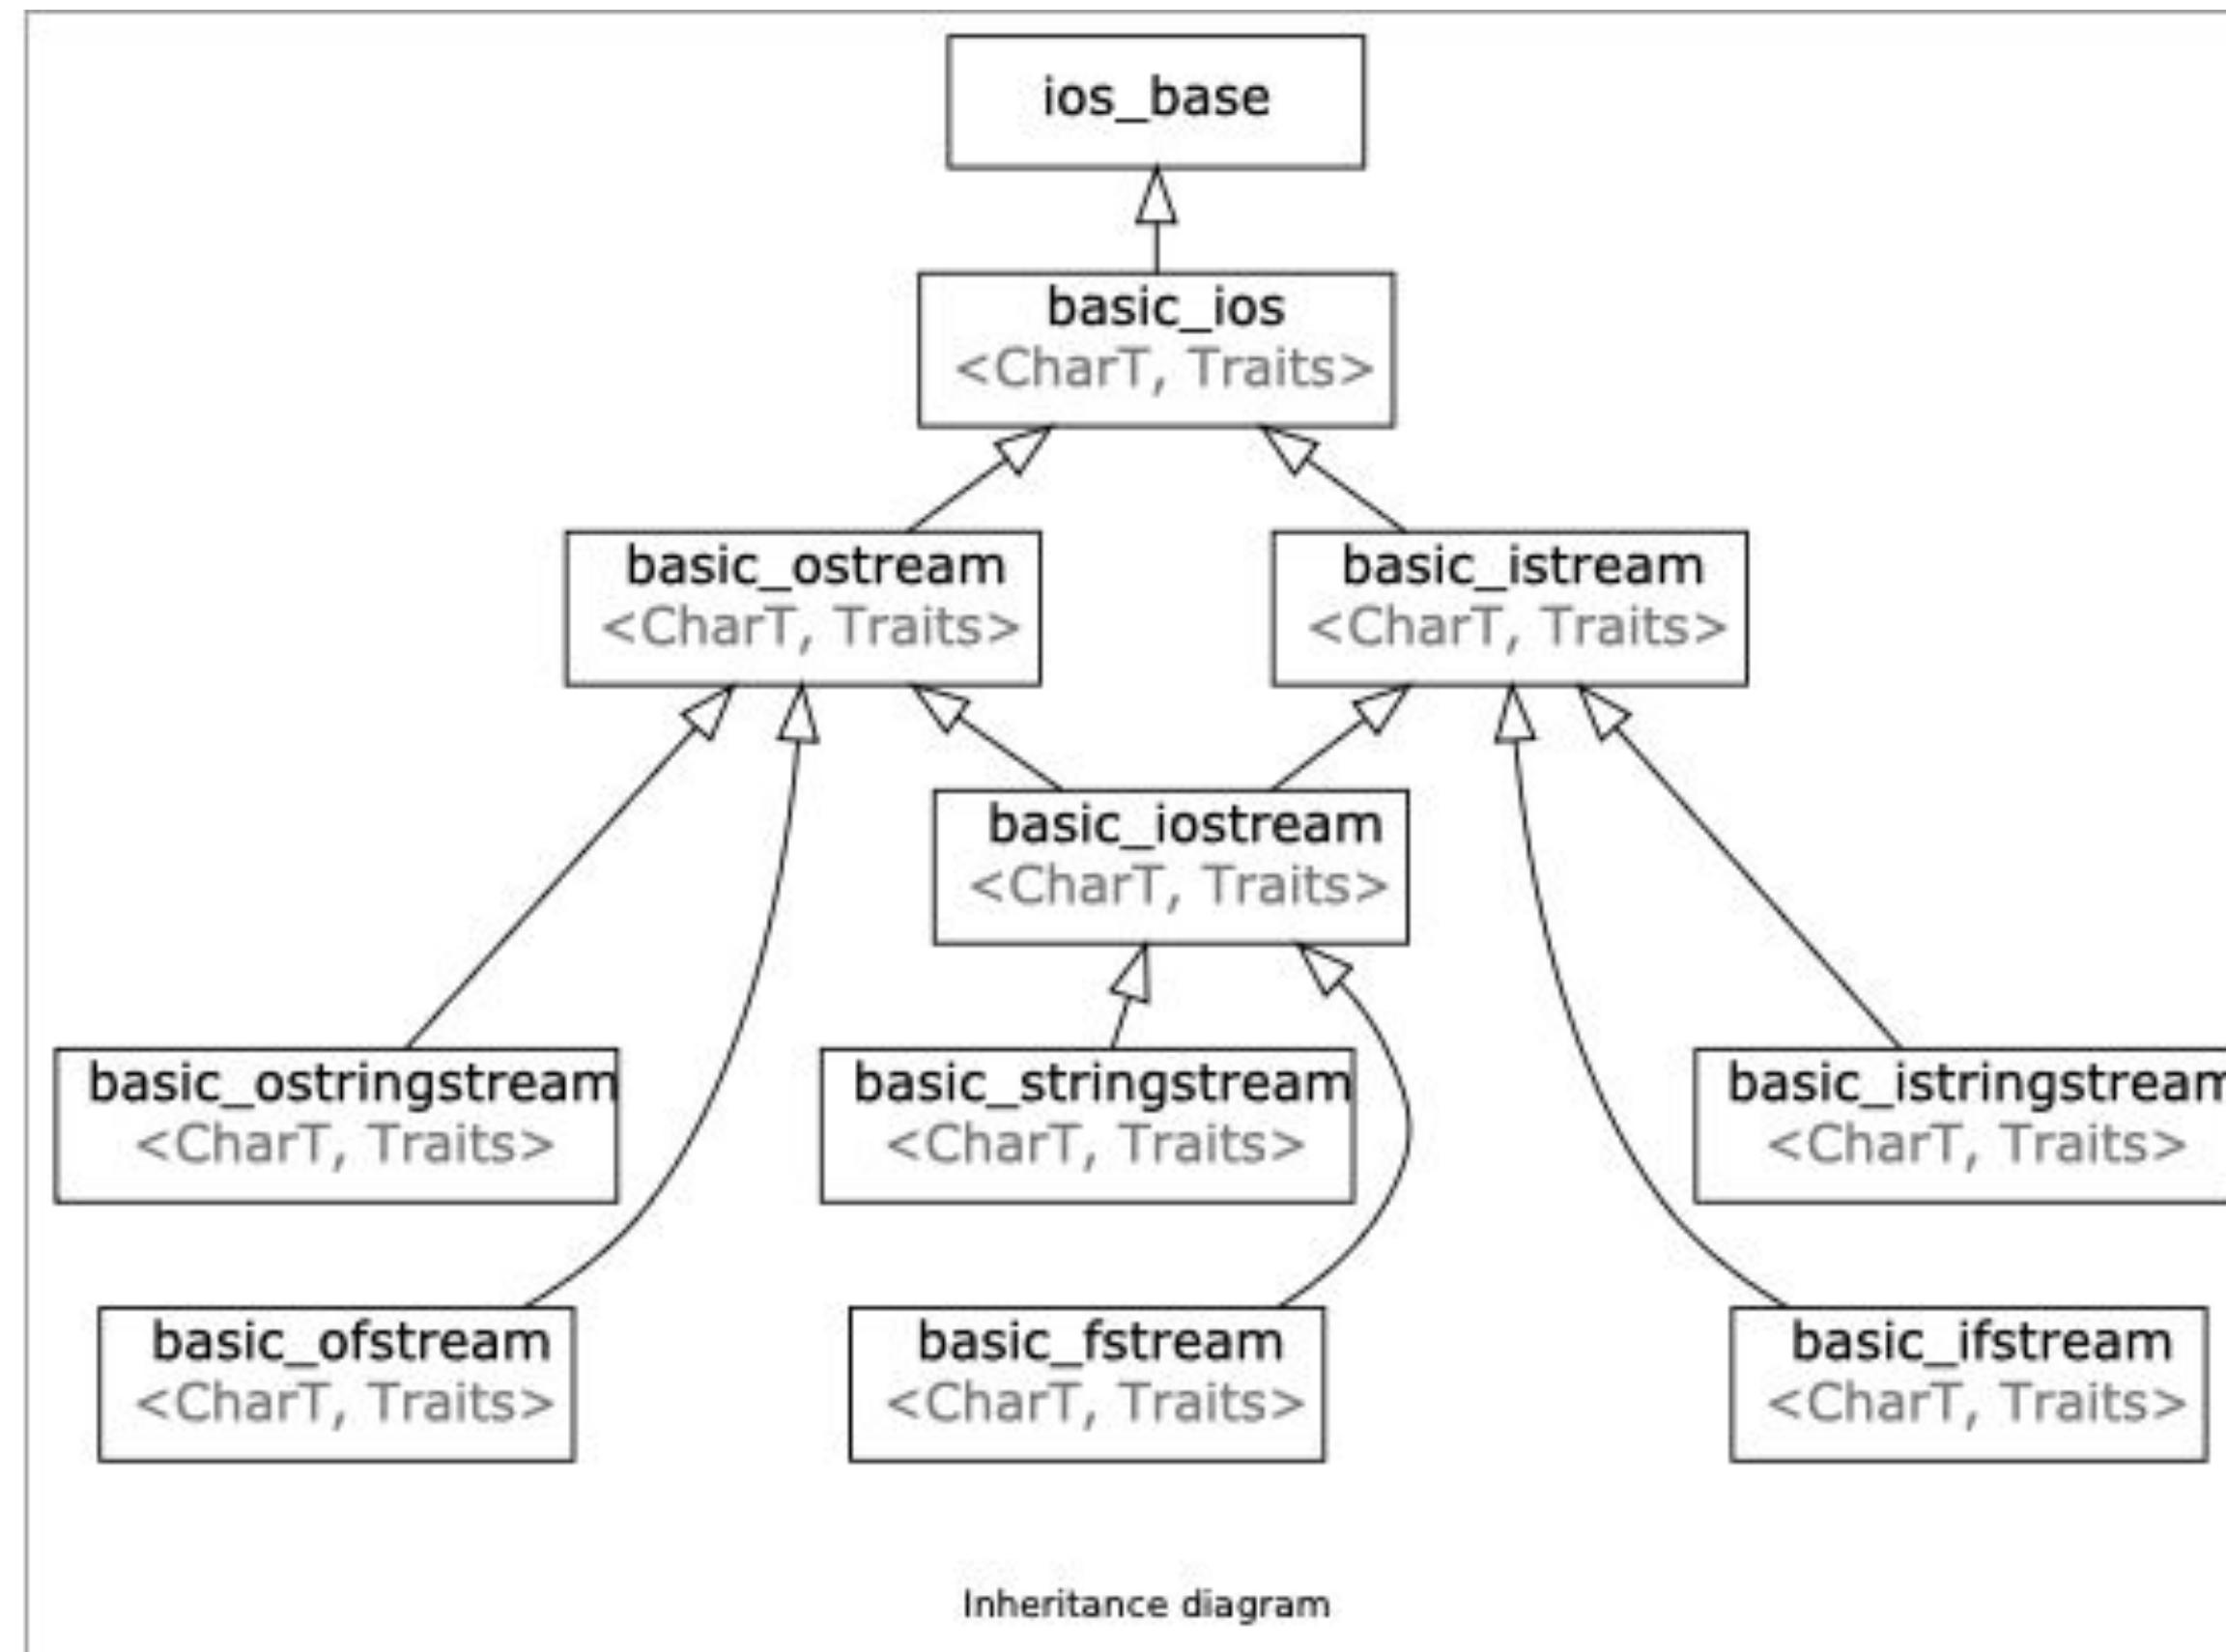

```
int main()
{
    double pi;
    std::cin >> pi;
    /// verify the value of pi!
    std::cout << pi / 2 << '\n';

    return 0;
}
```

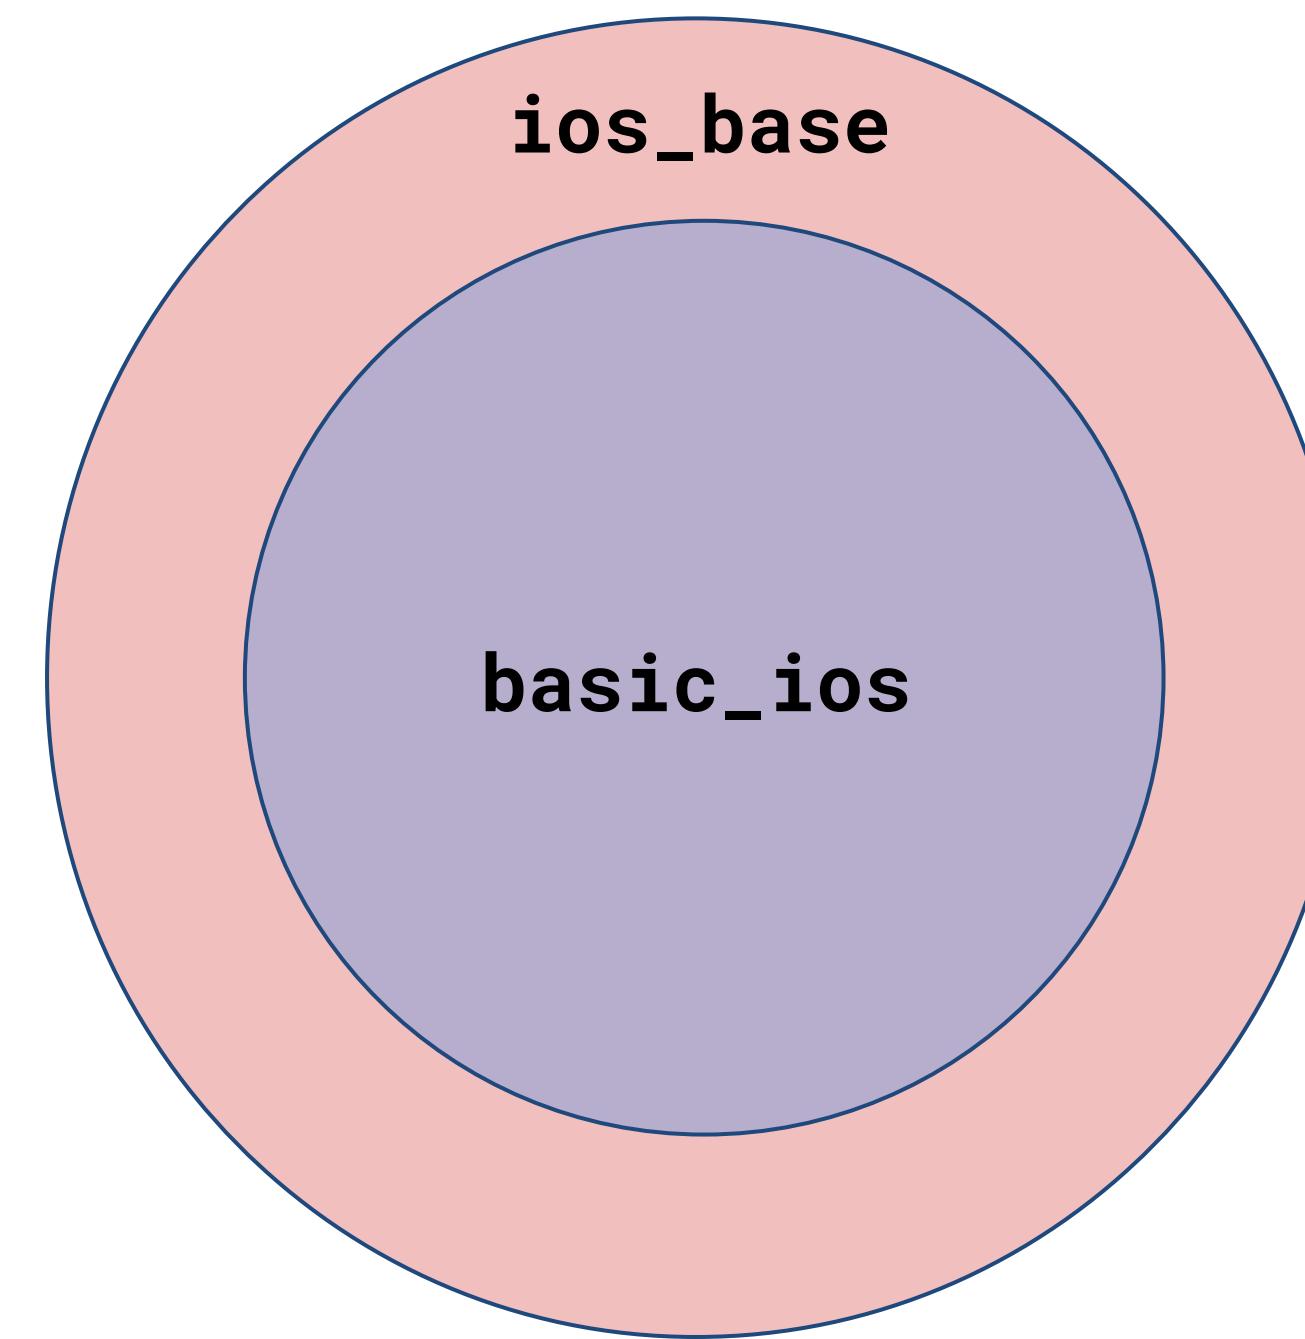

“1.57”

Console

What streams actually are

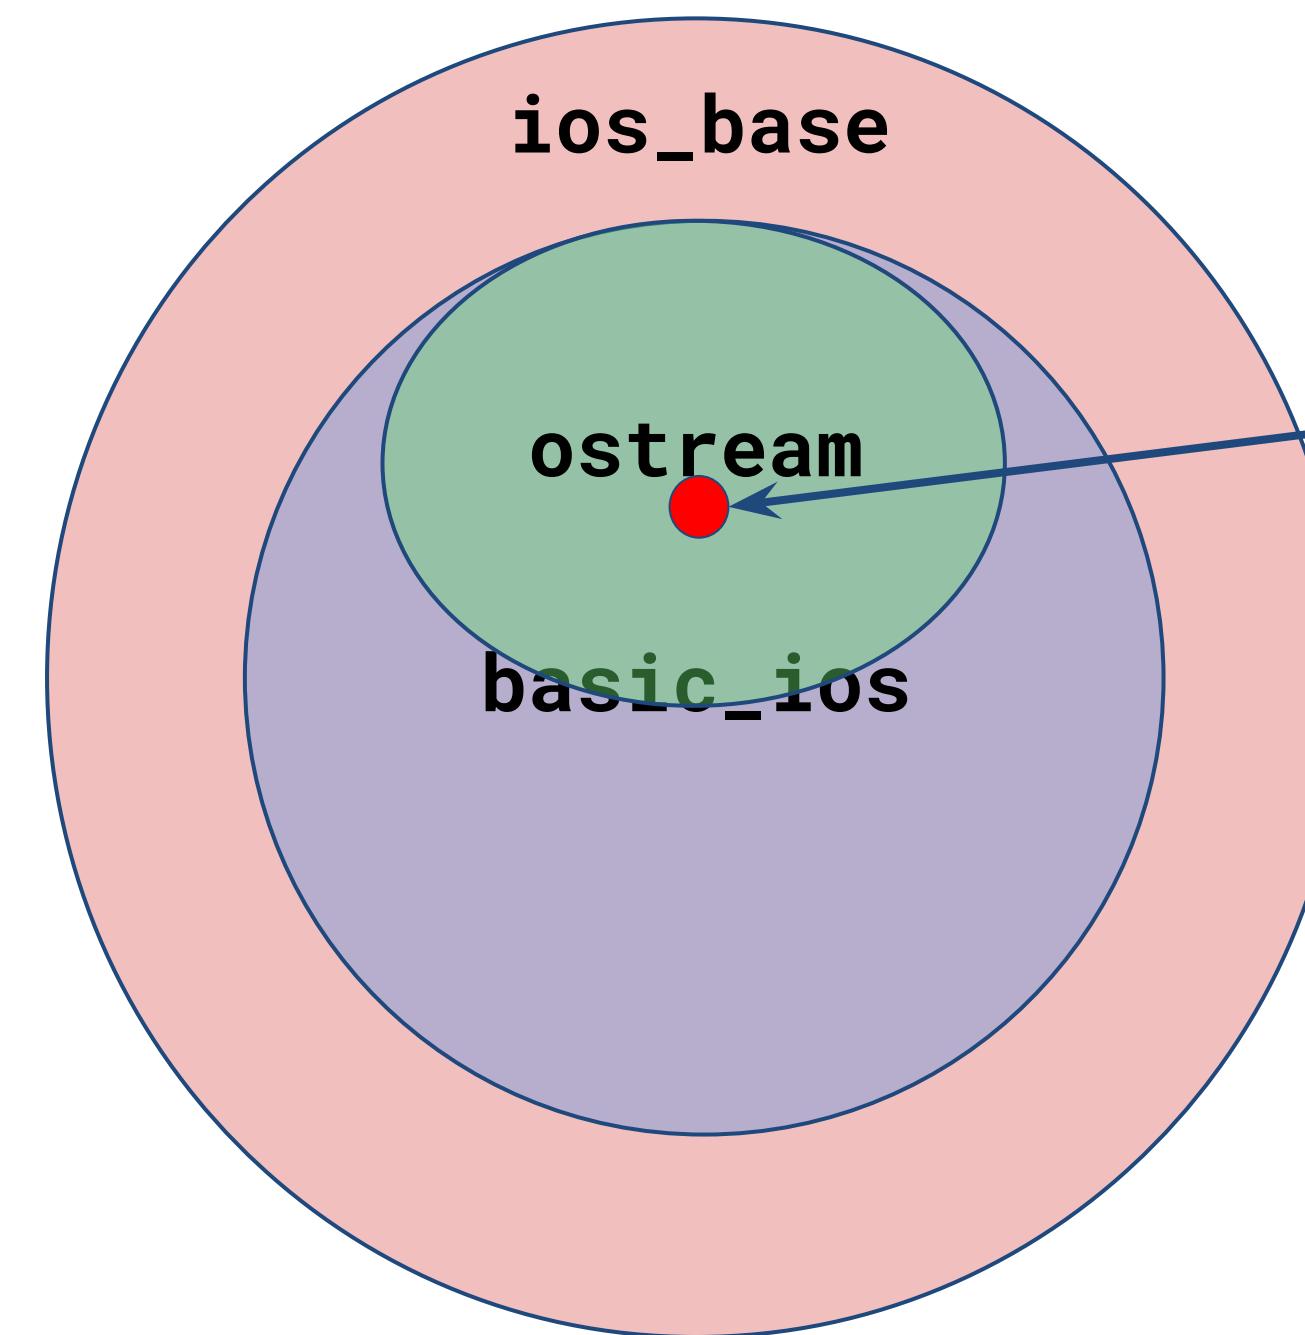

streams and types

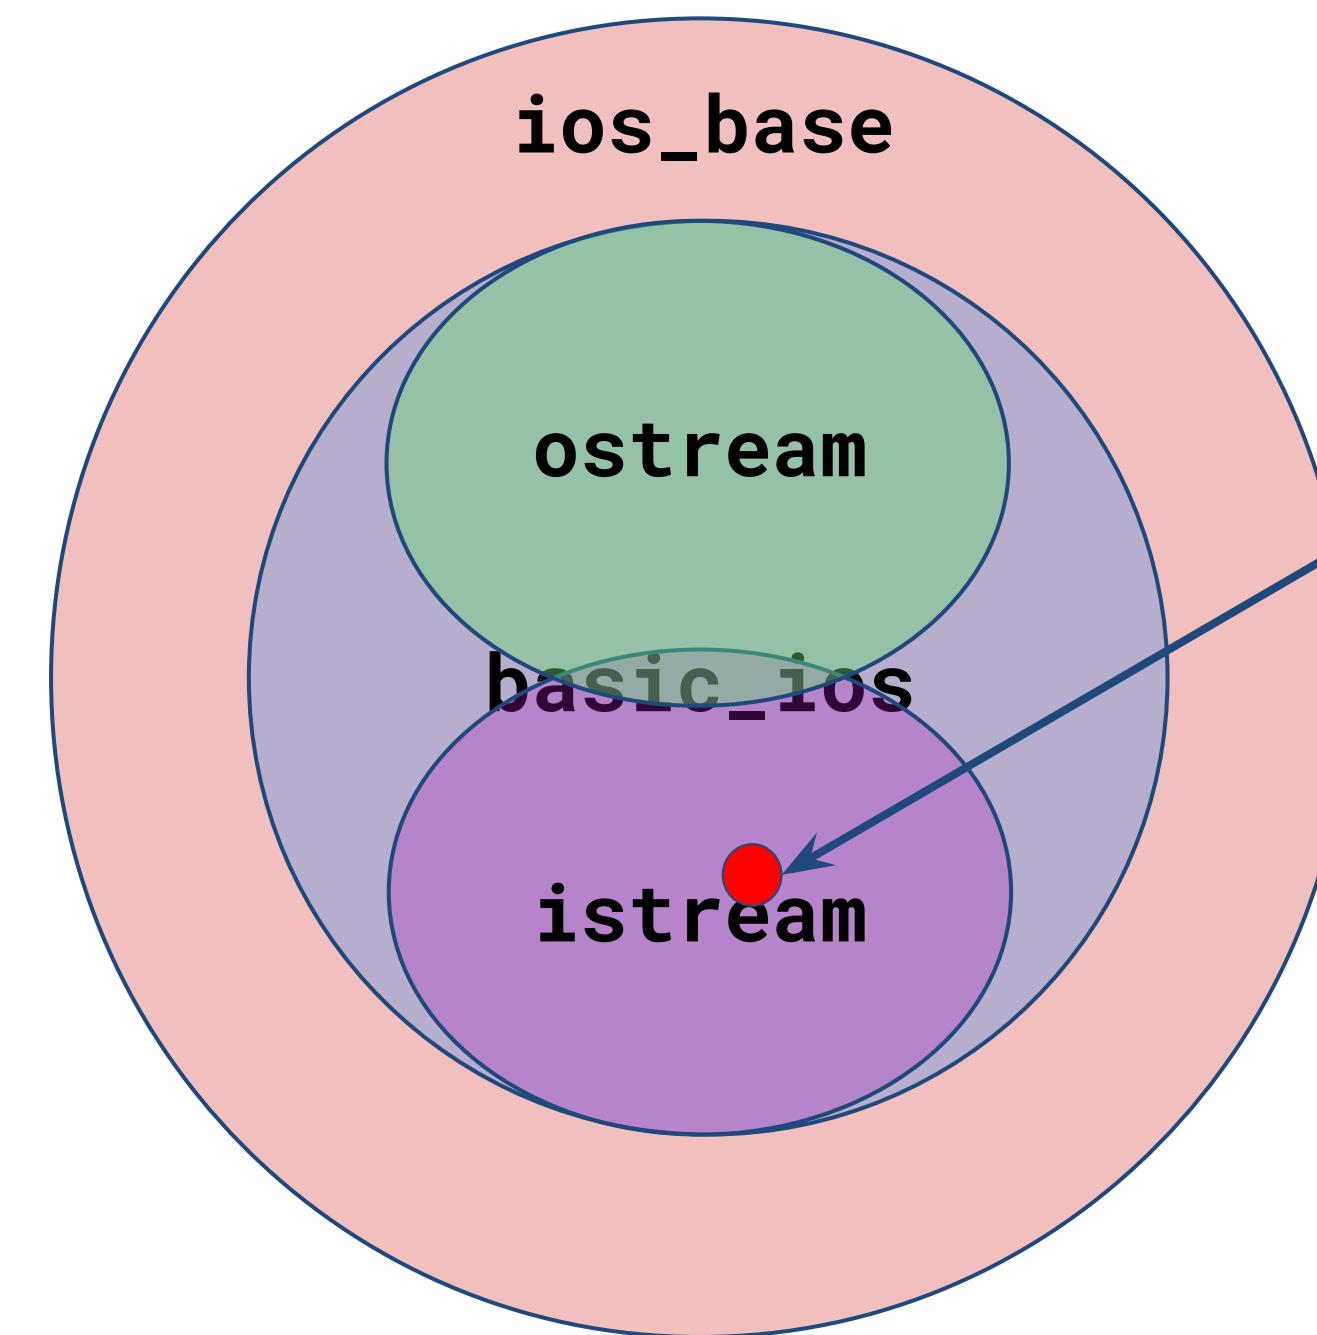

Each of these types are associated
with some functionality – more on
this later

streams and types

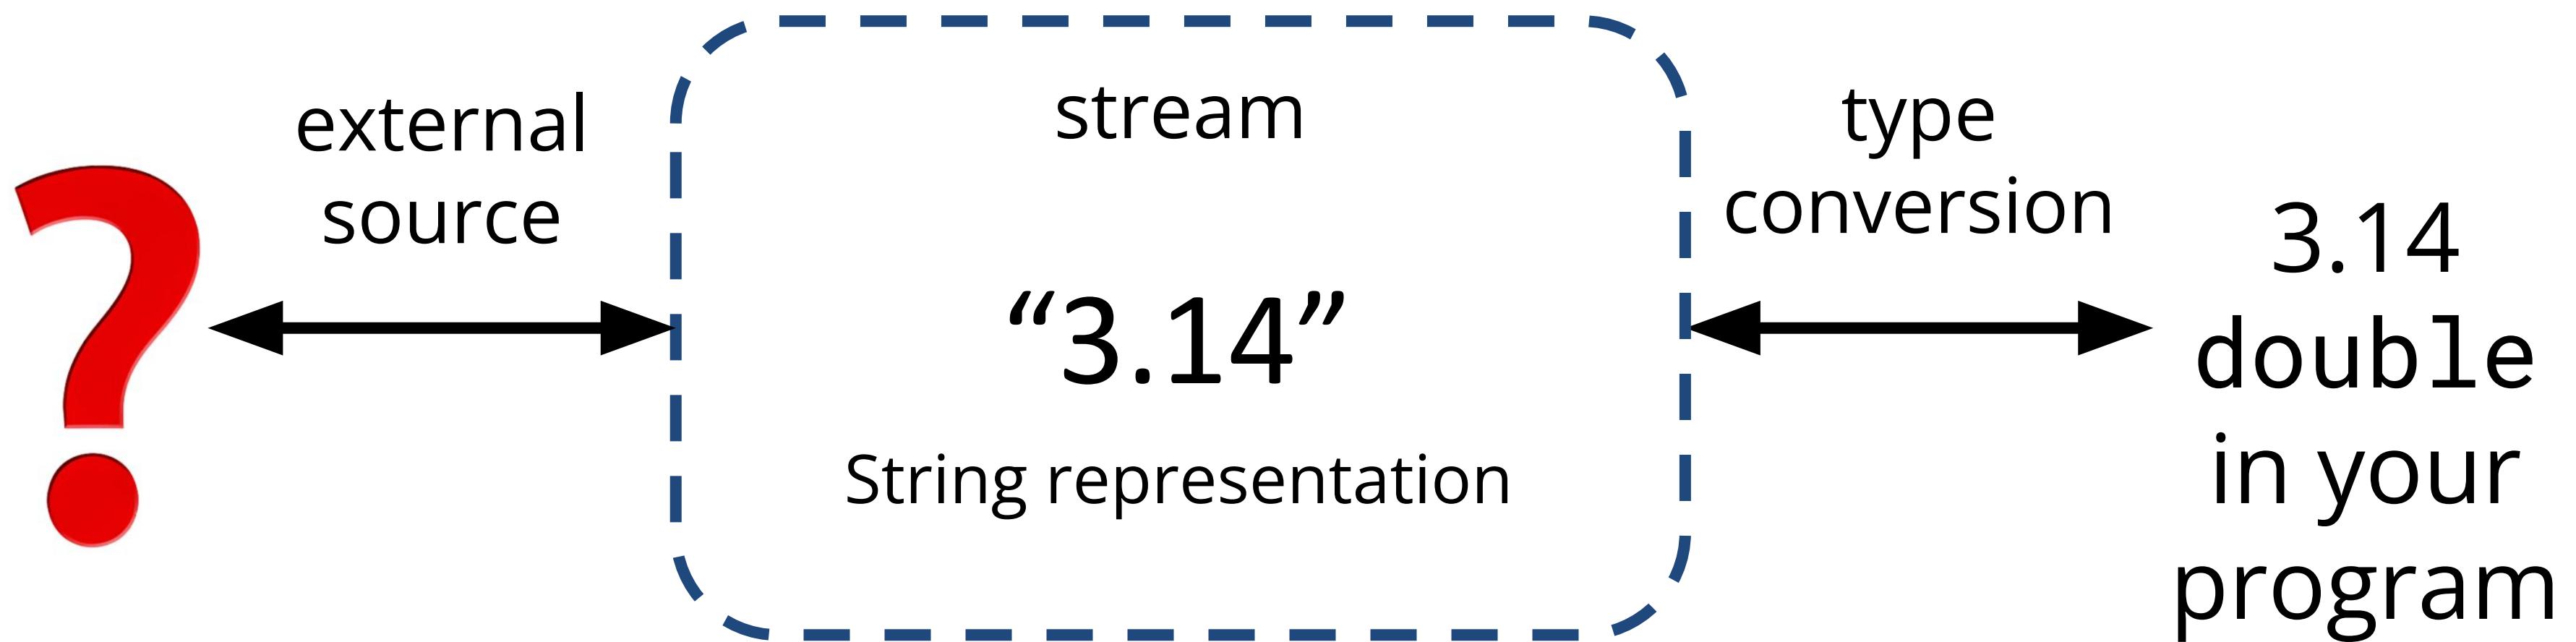

std::cout has the property of the
std::basic_ostream type

streams and types

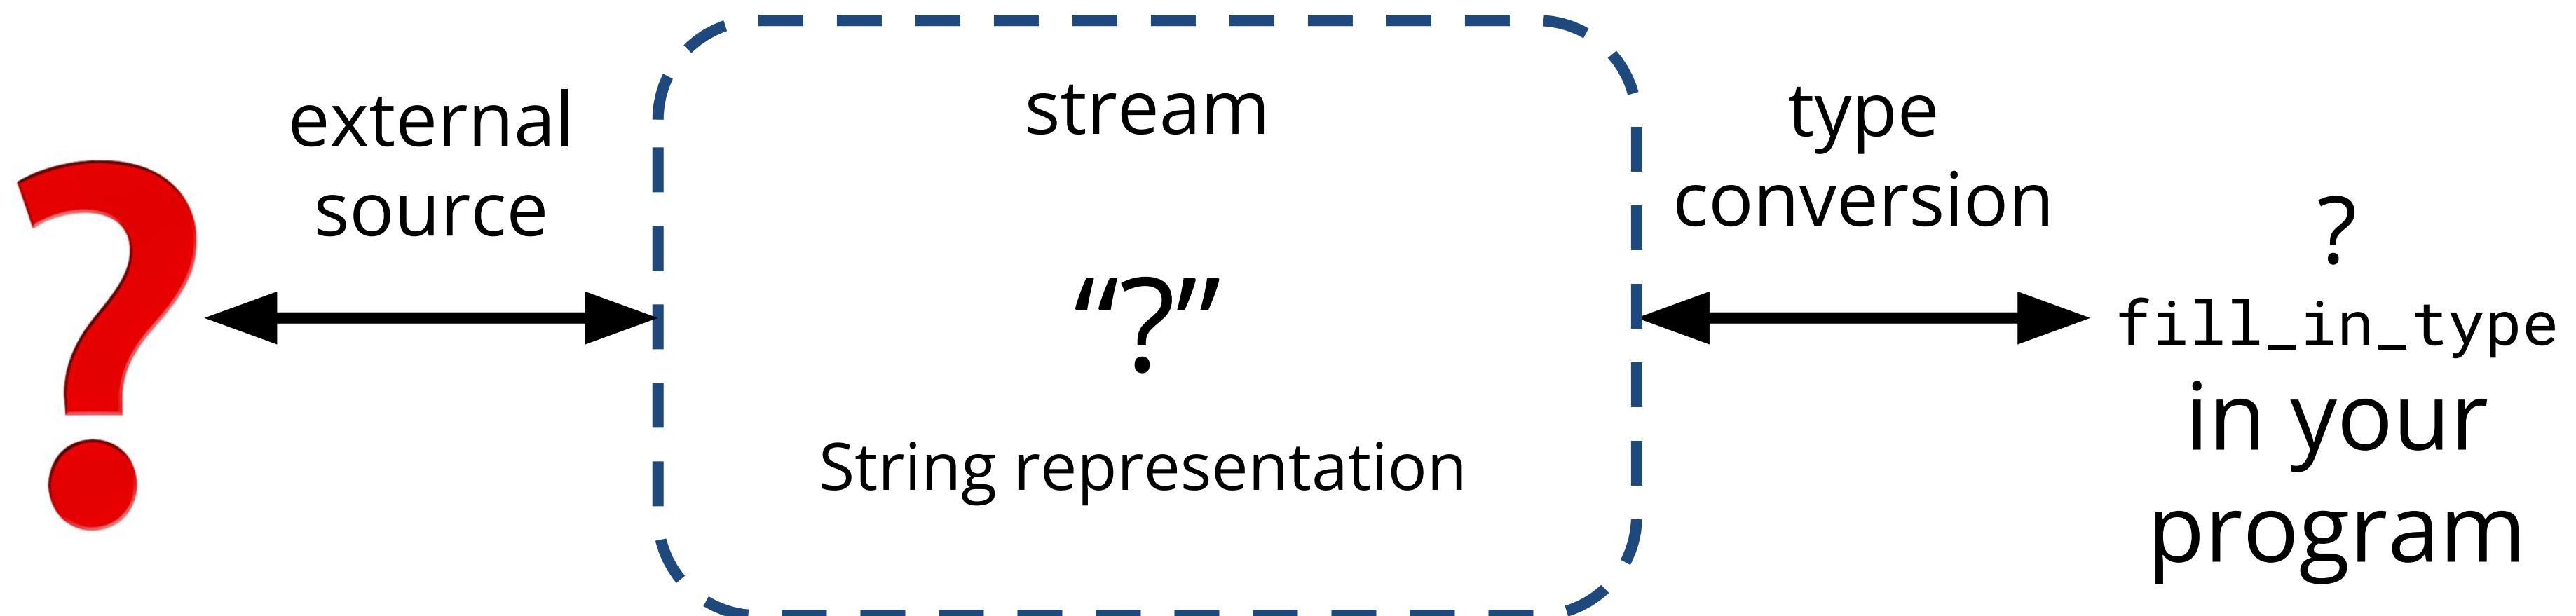

`std::cin` has the property of the
`std::istream` type

Generalizing the Stream

Implementation vs Abstraction

Why is this even useful?

Streams allow for a **universal** way of **dealing with external data**

What streams actually are

Classifying different types of streams

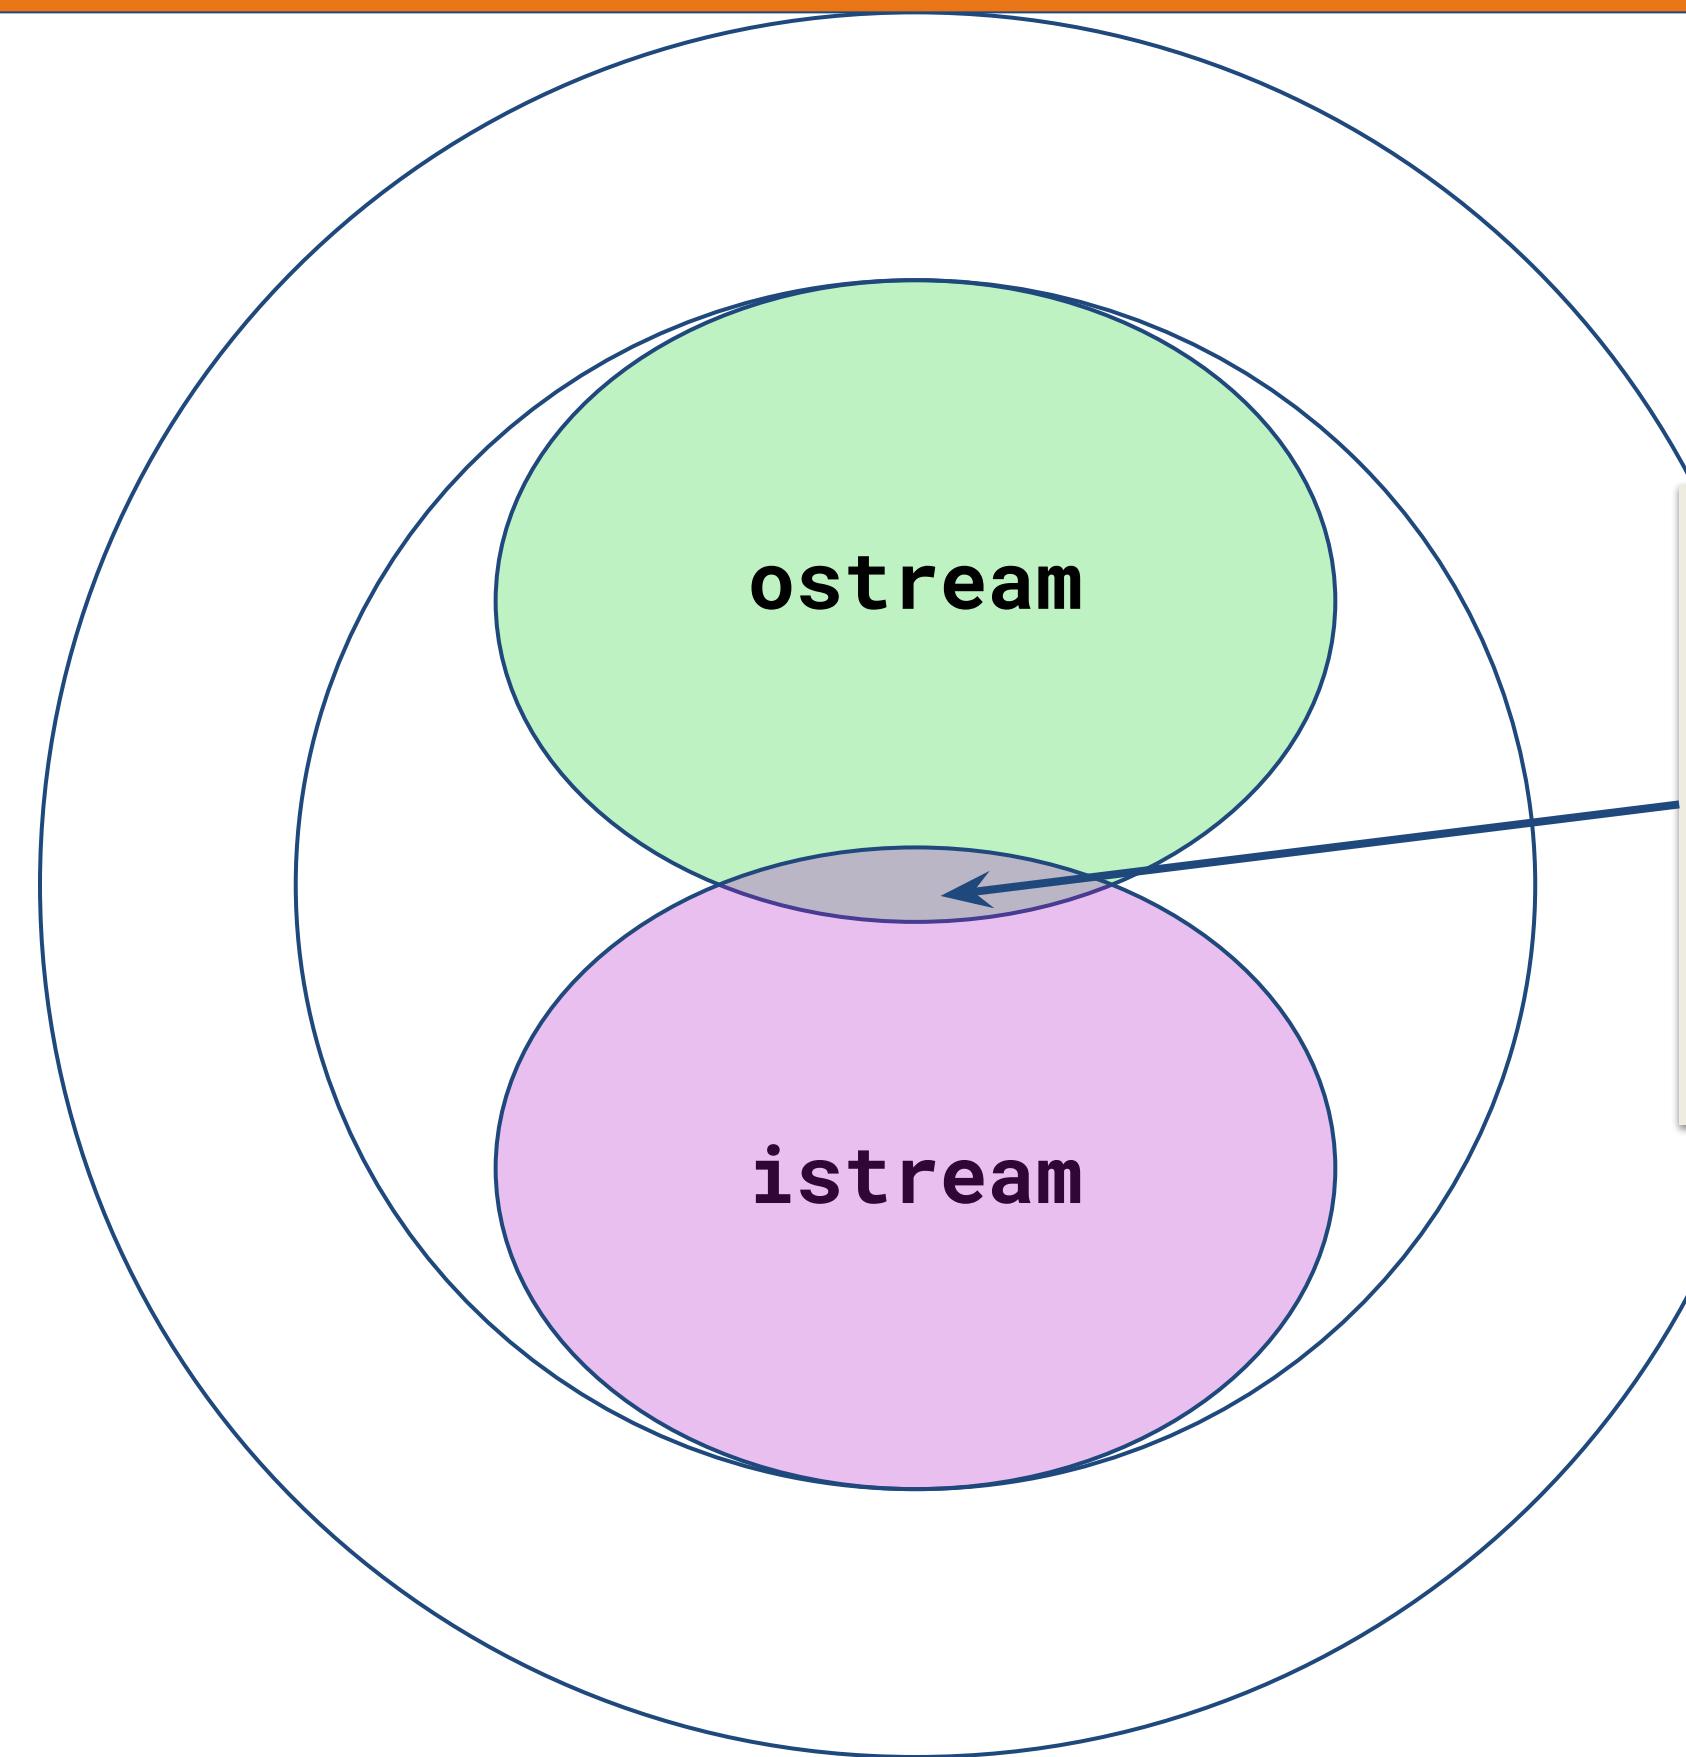

Input streams (I)

- a way to read data from a source
 - Are inherited from **std::istream**
 - ex. reading in something from the console (**std::cin**)
 - primary operator: **>>** (called the extraction operator)

Output streams (O)

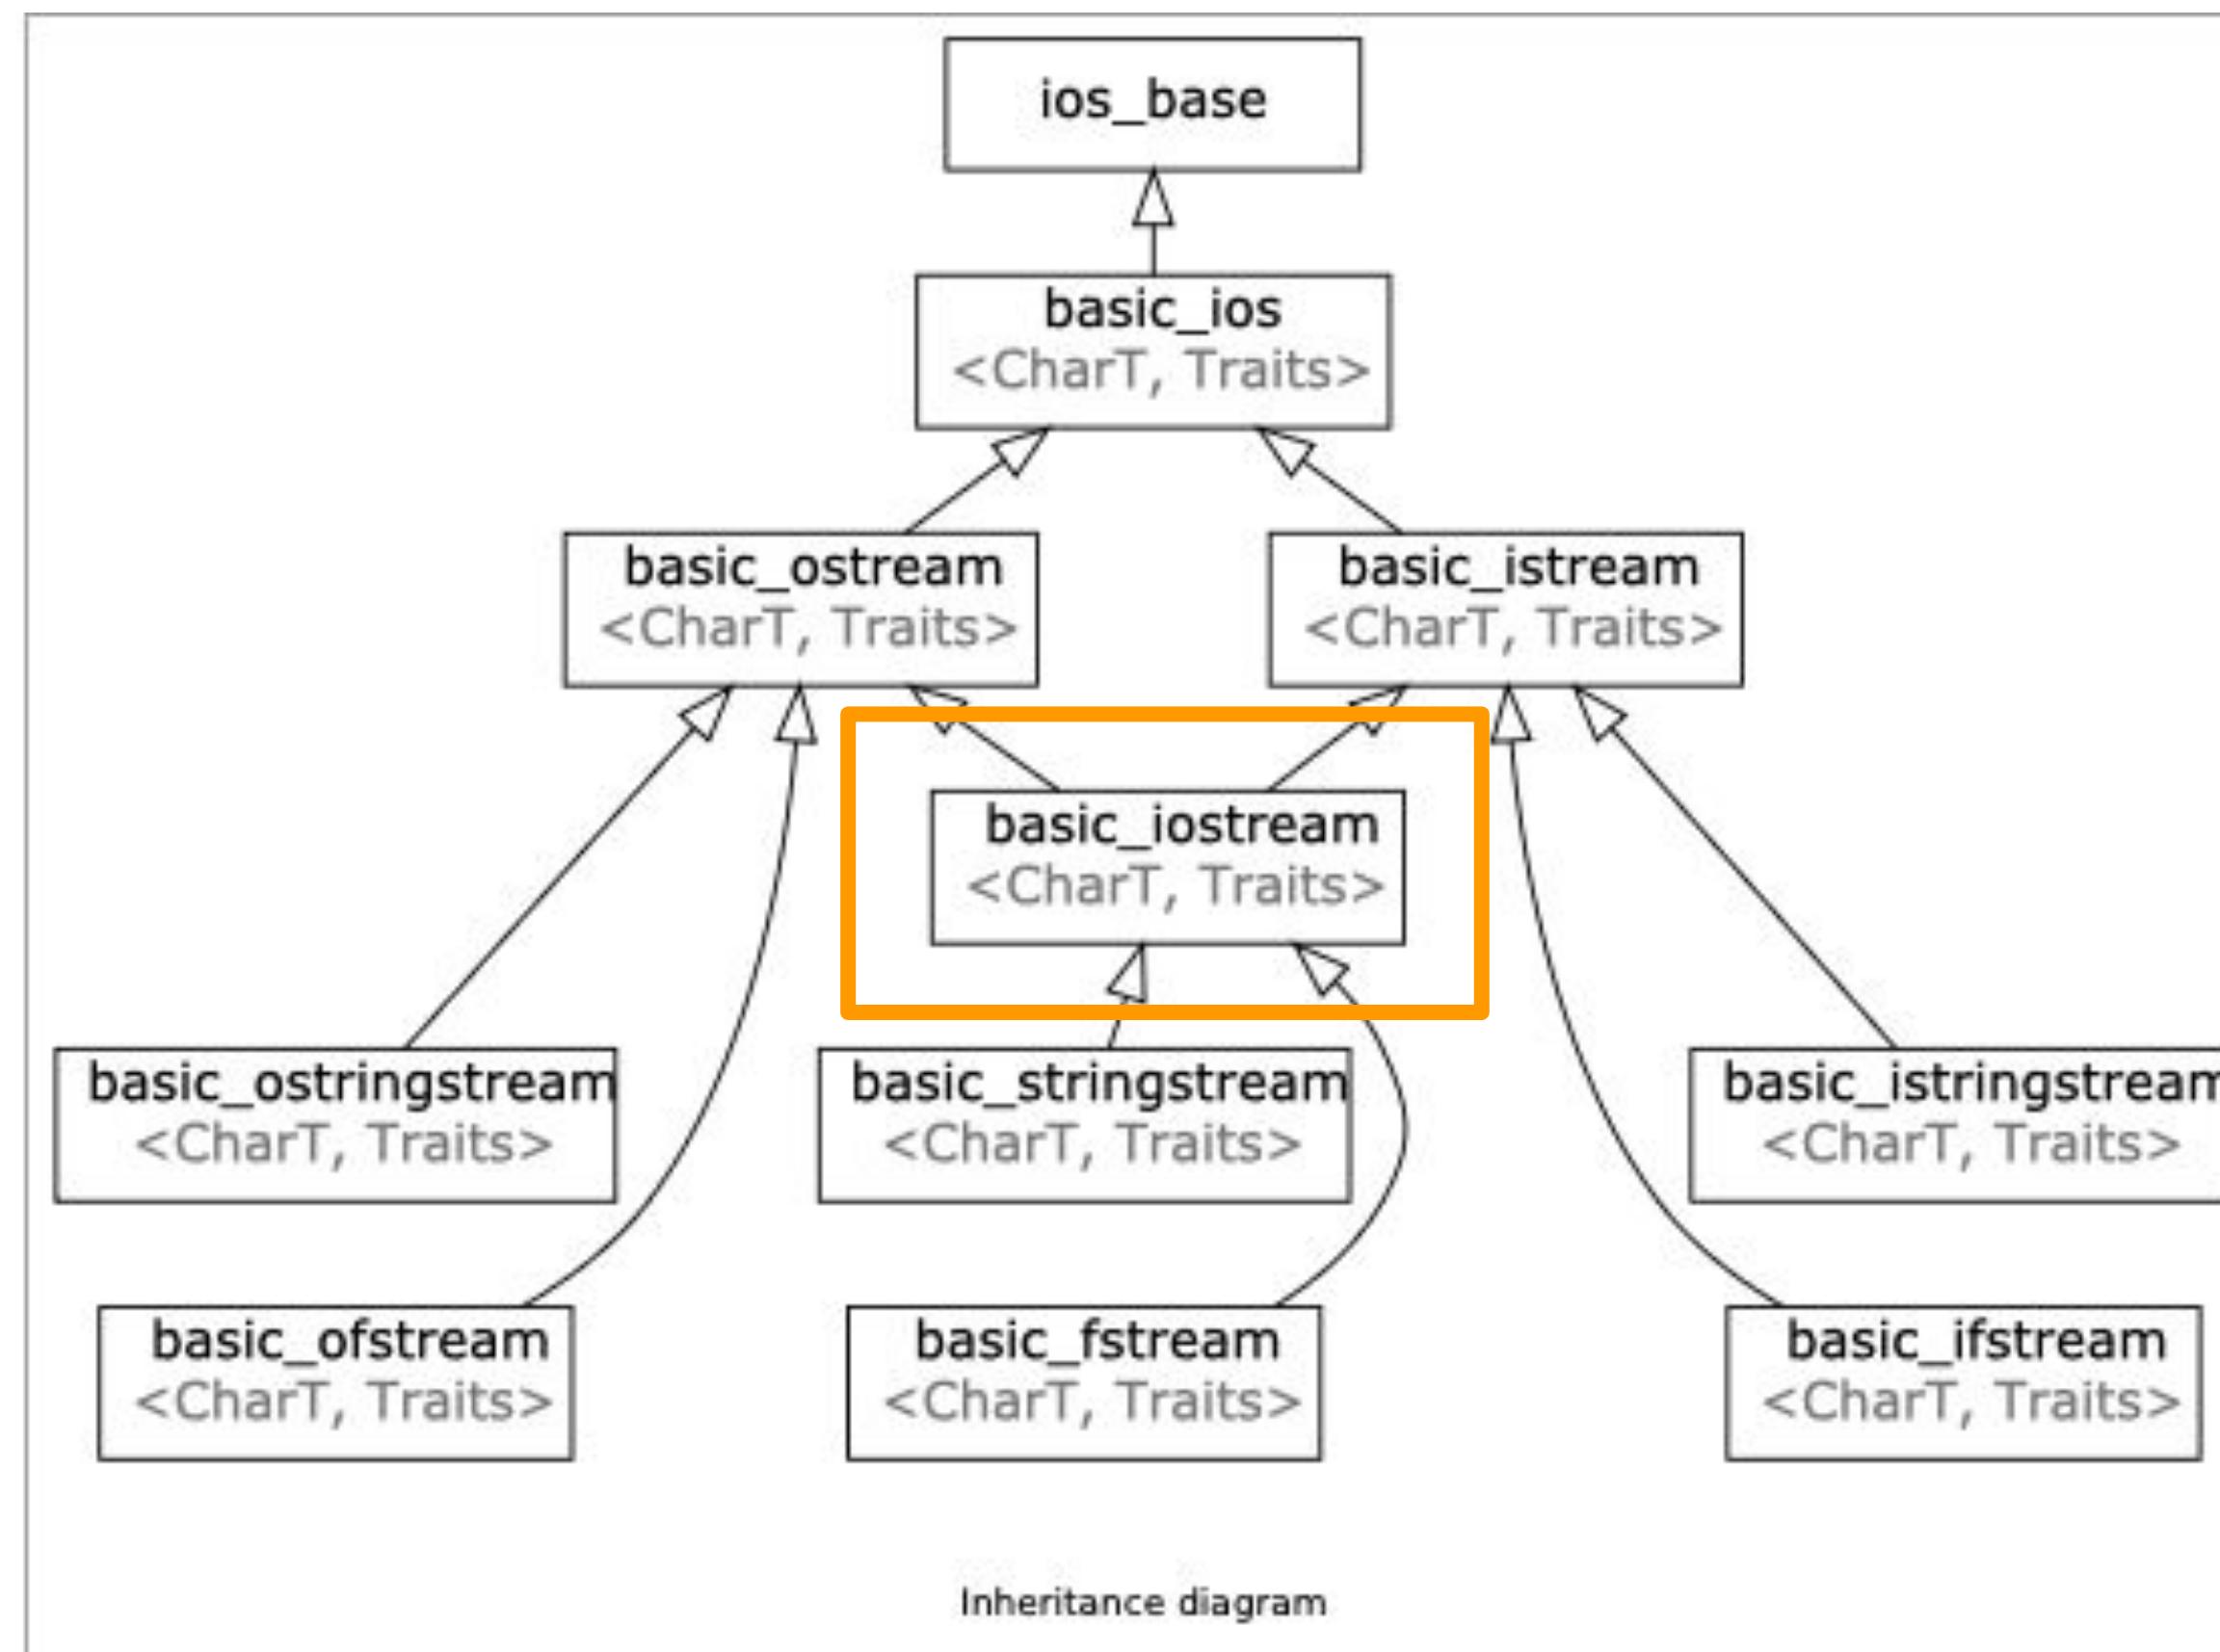

- a way to write data to a destination
 - Are inherited from **std::ostream**
 - ex. writing out something to the console (**std::cout**)
 - primary operator: **<<** (called the insertion operator)

streams and types

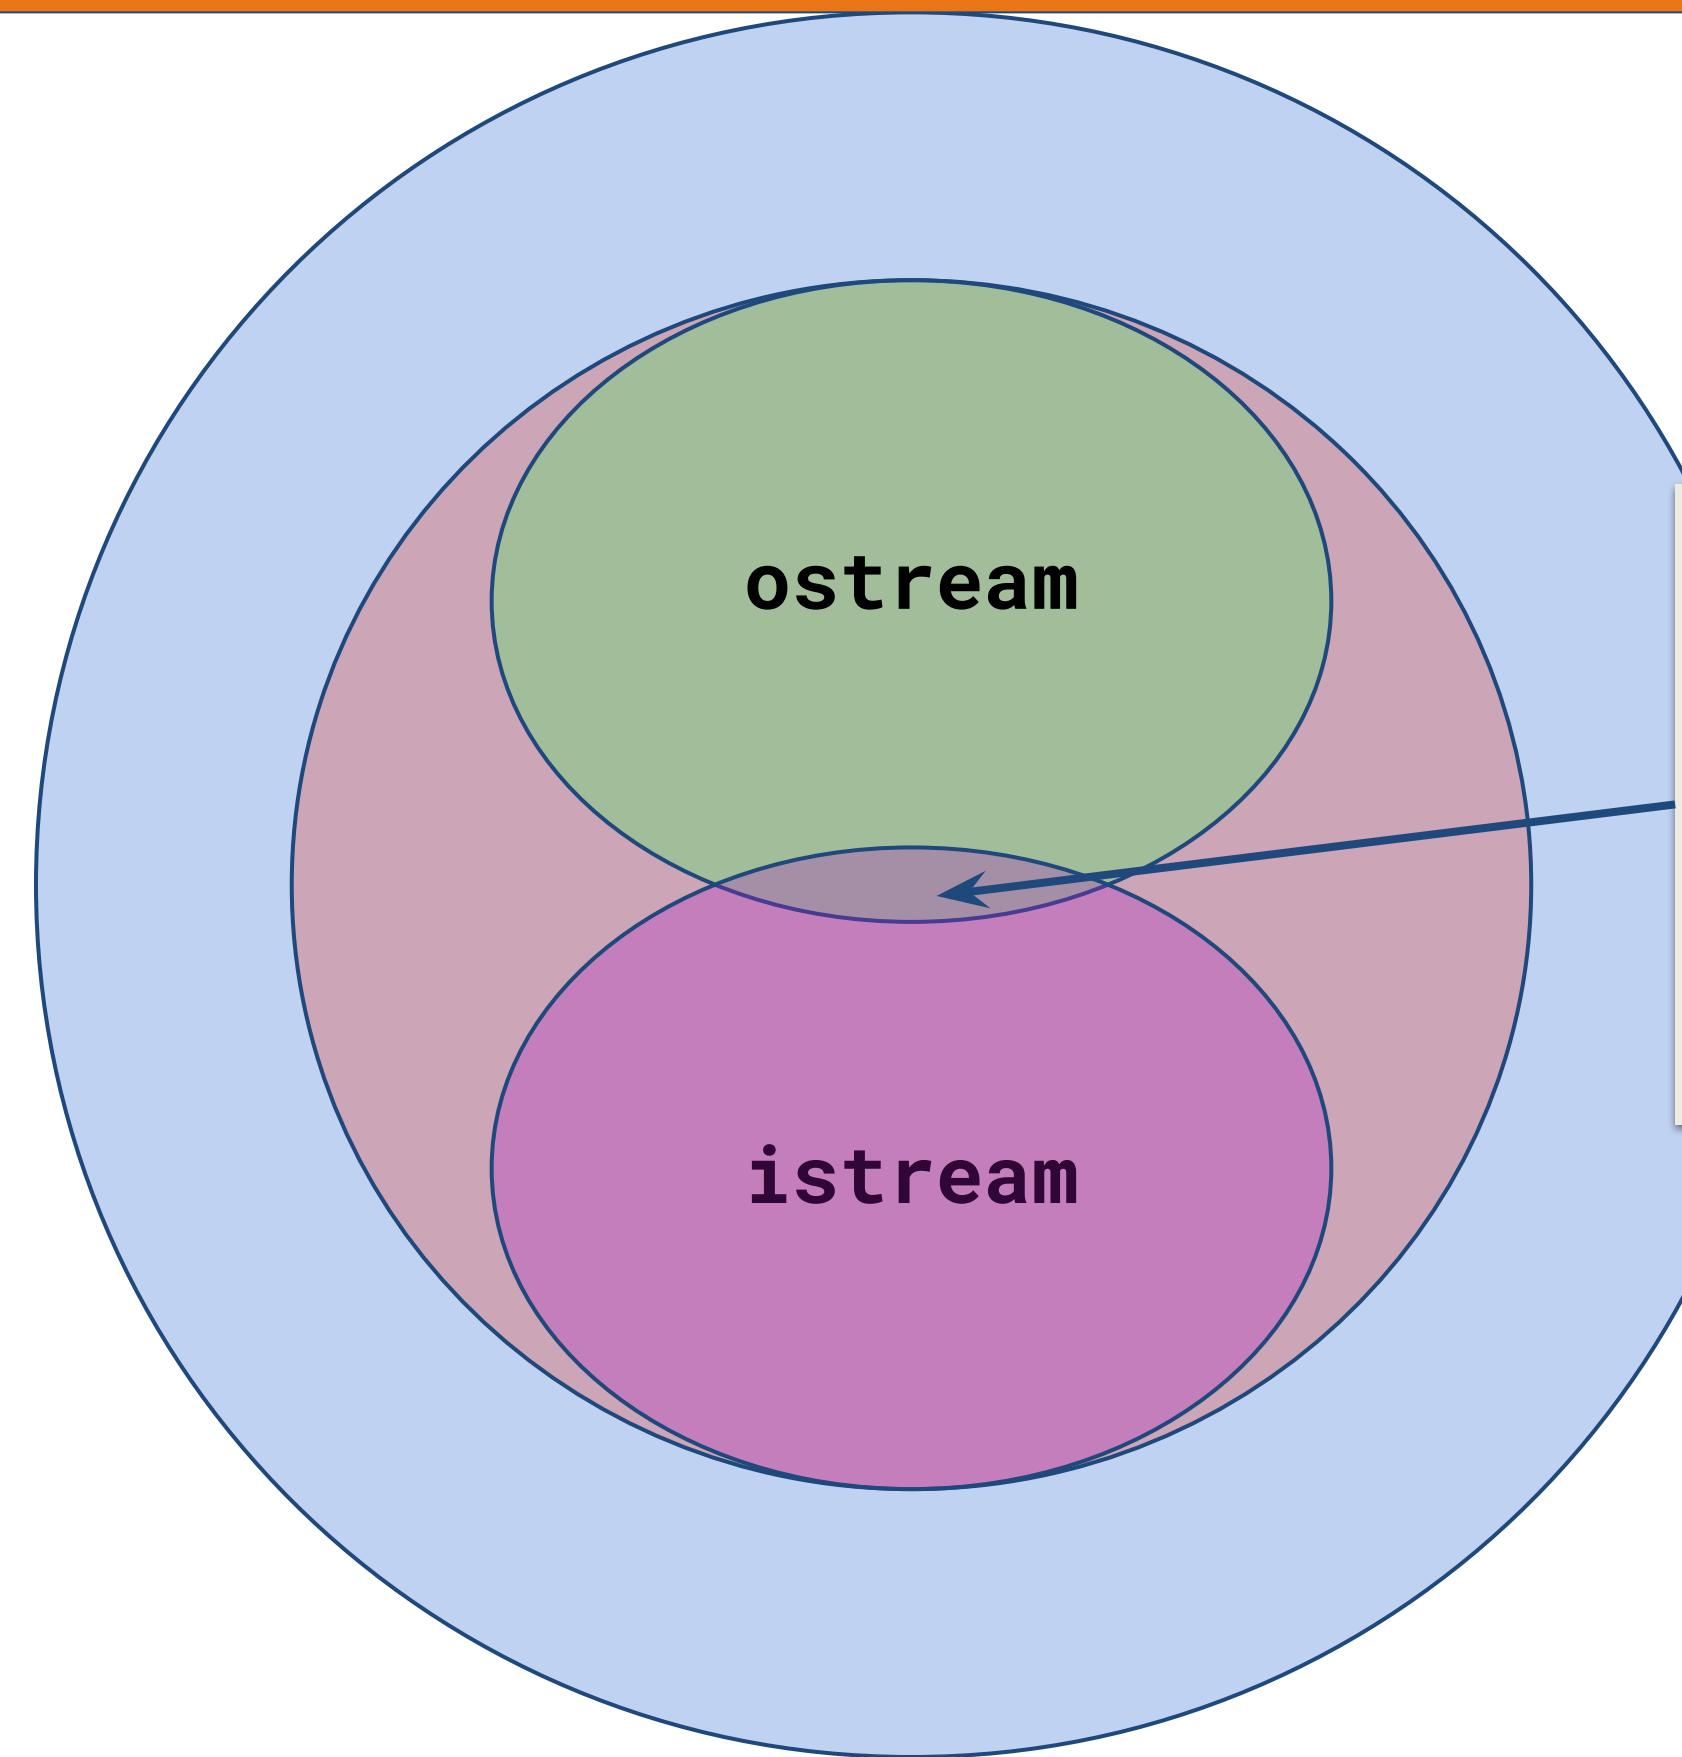

This intersection is known as **iostream** which takes has all of the characteristics of **ostream** and **istream**!

What streams actually are

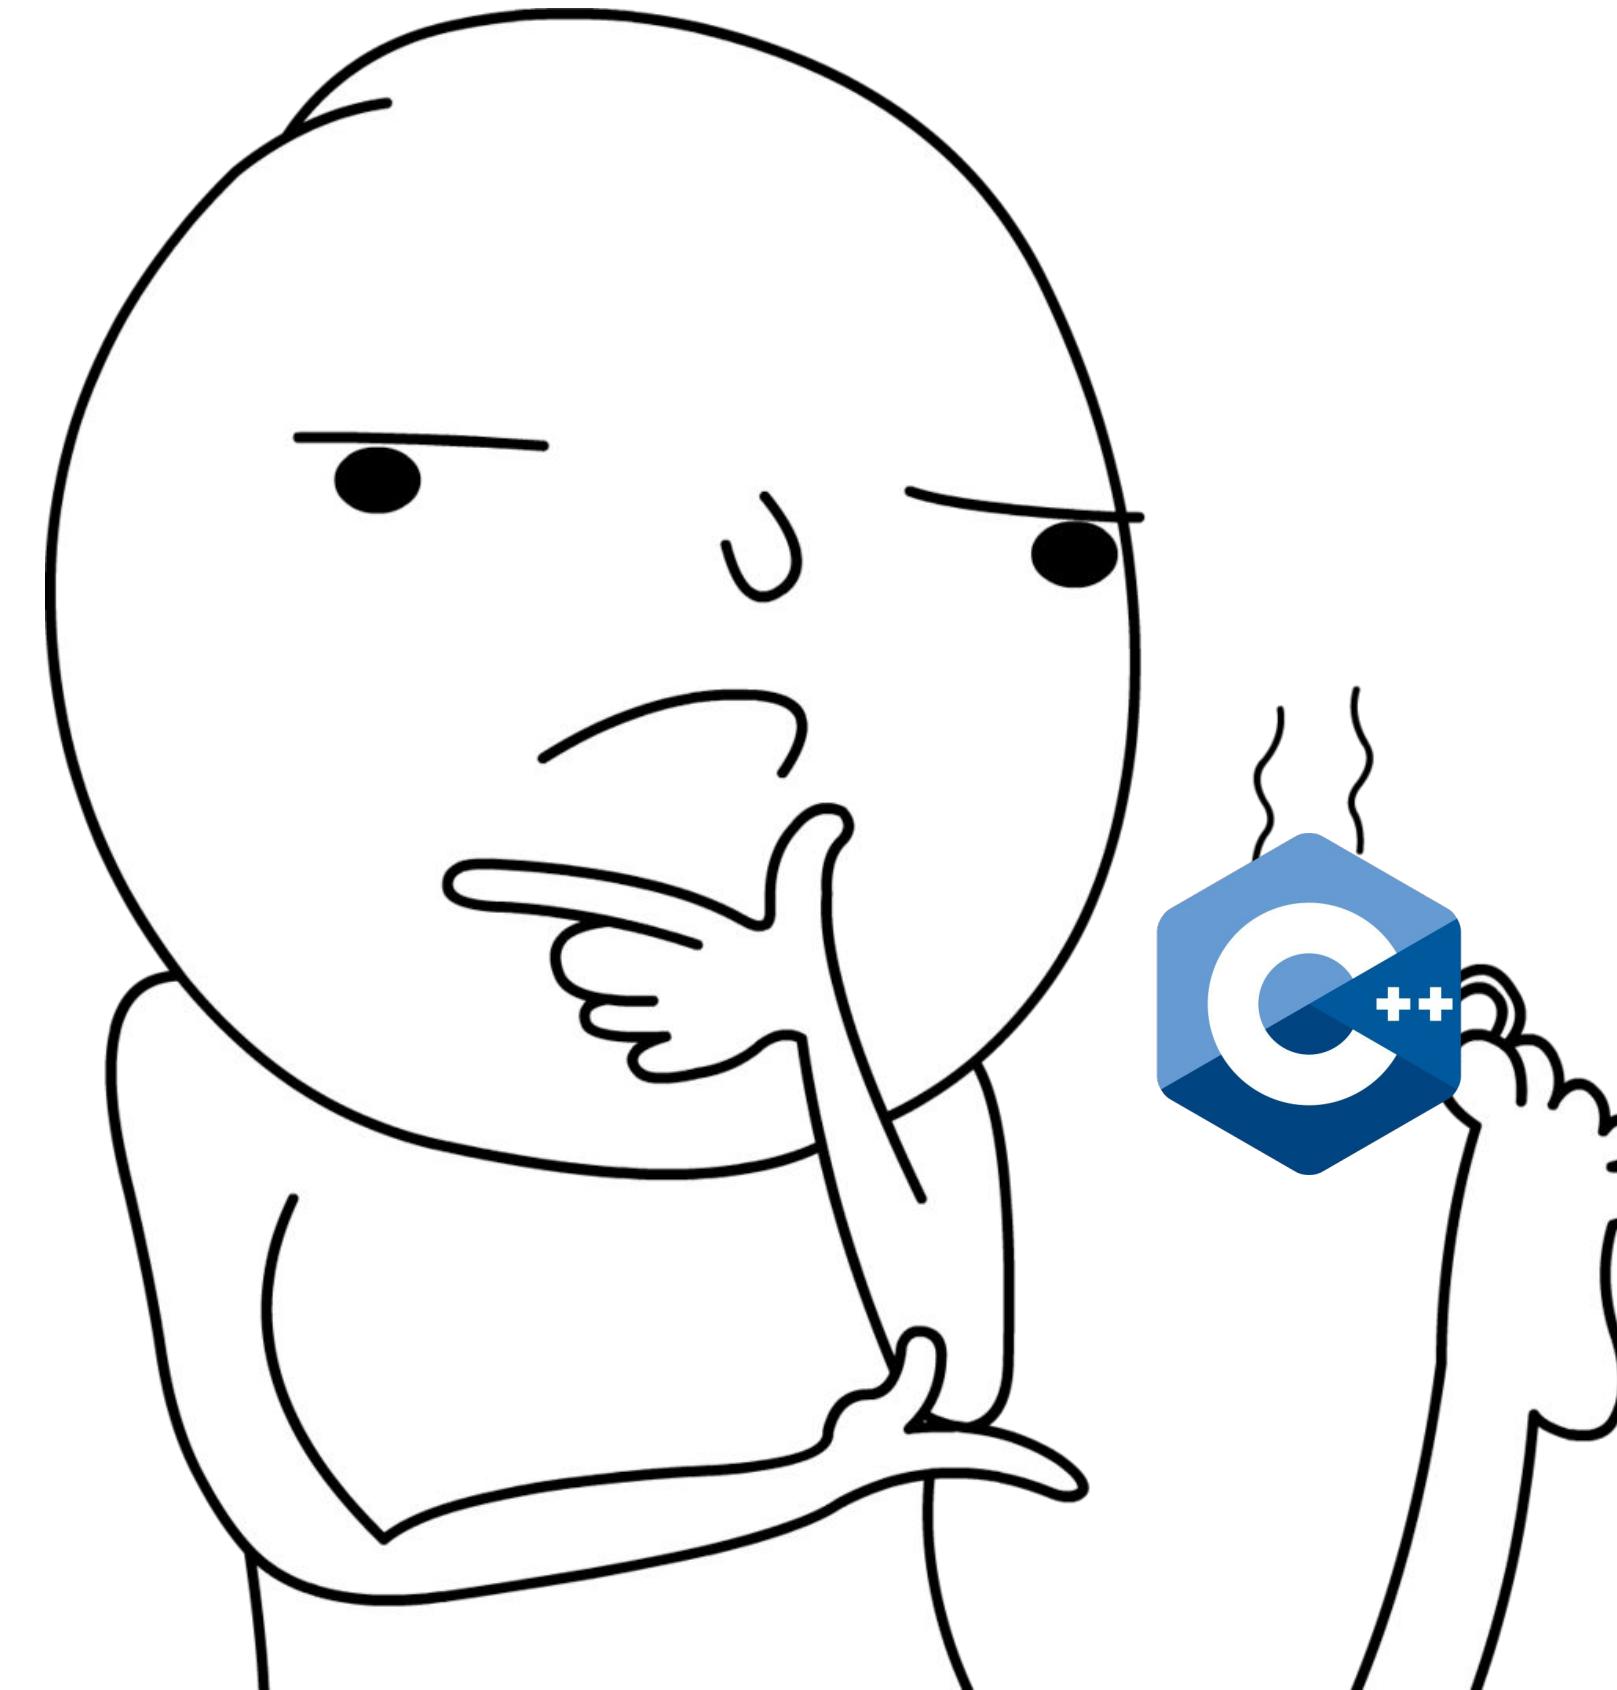

streams and types

This intersection is known as **iostream** which takes has all of the characteristics of **ostream** and **istream**!

What questions do we have?

Plan

1. Quick recap
2. What are streams??!!
3. **stringstreams!**
4. cout and cin
5. Output streams
6. Input streams

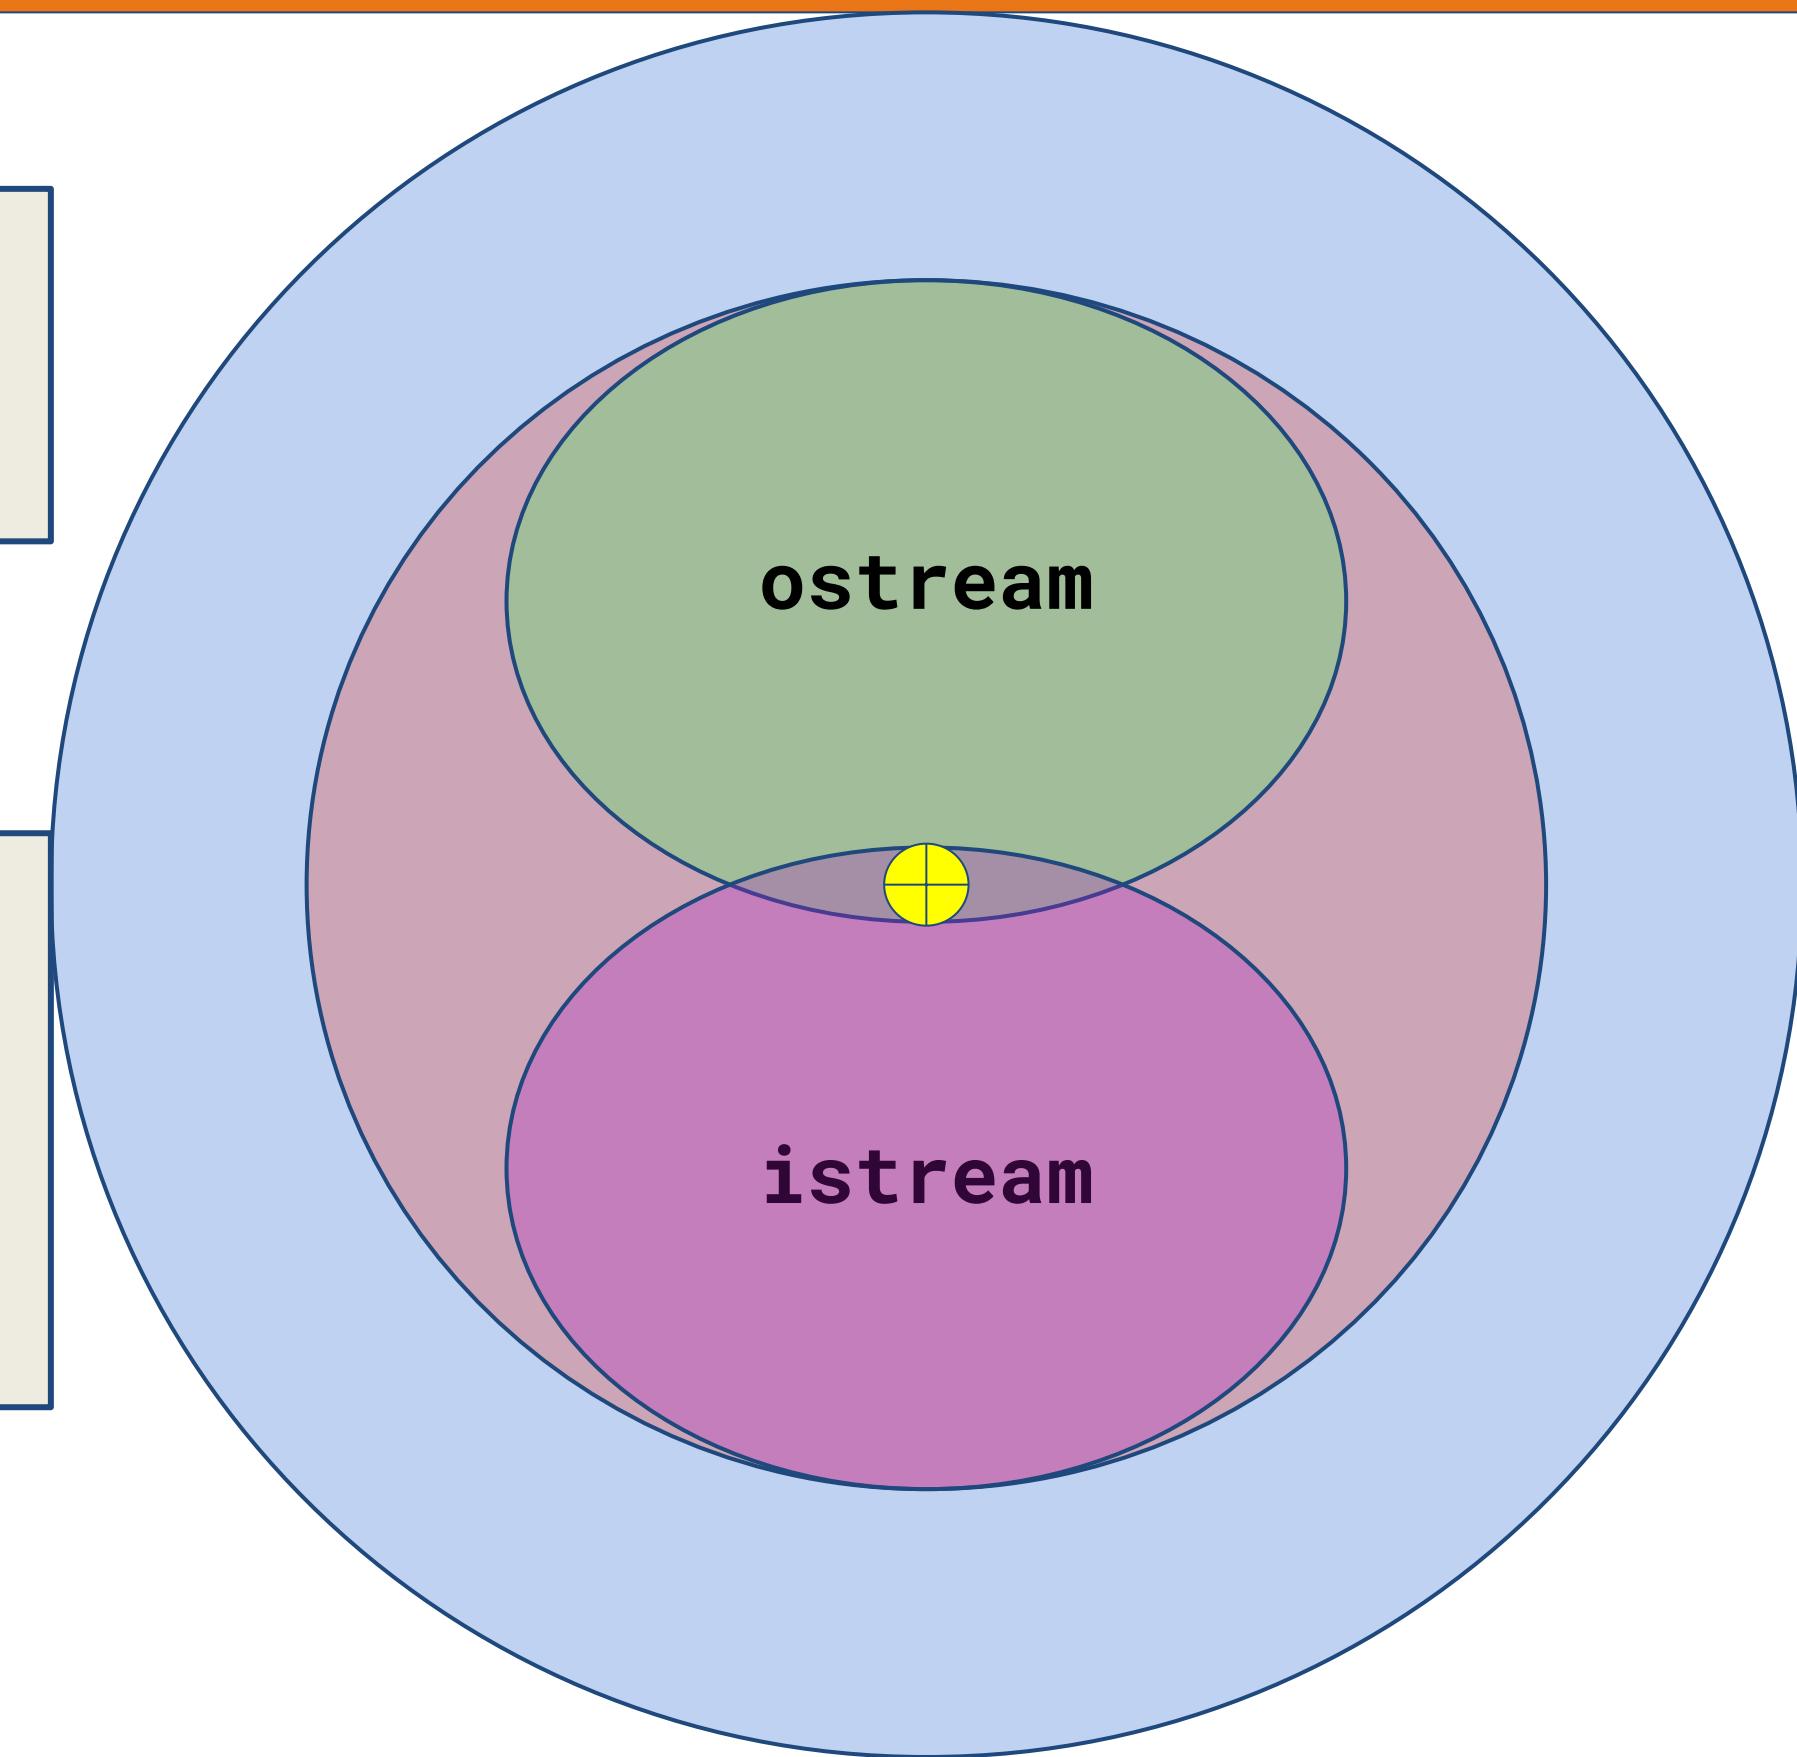

`std::stringstream`

What?

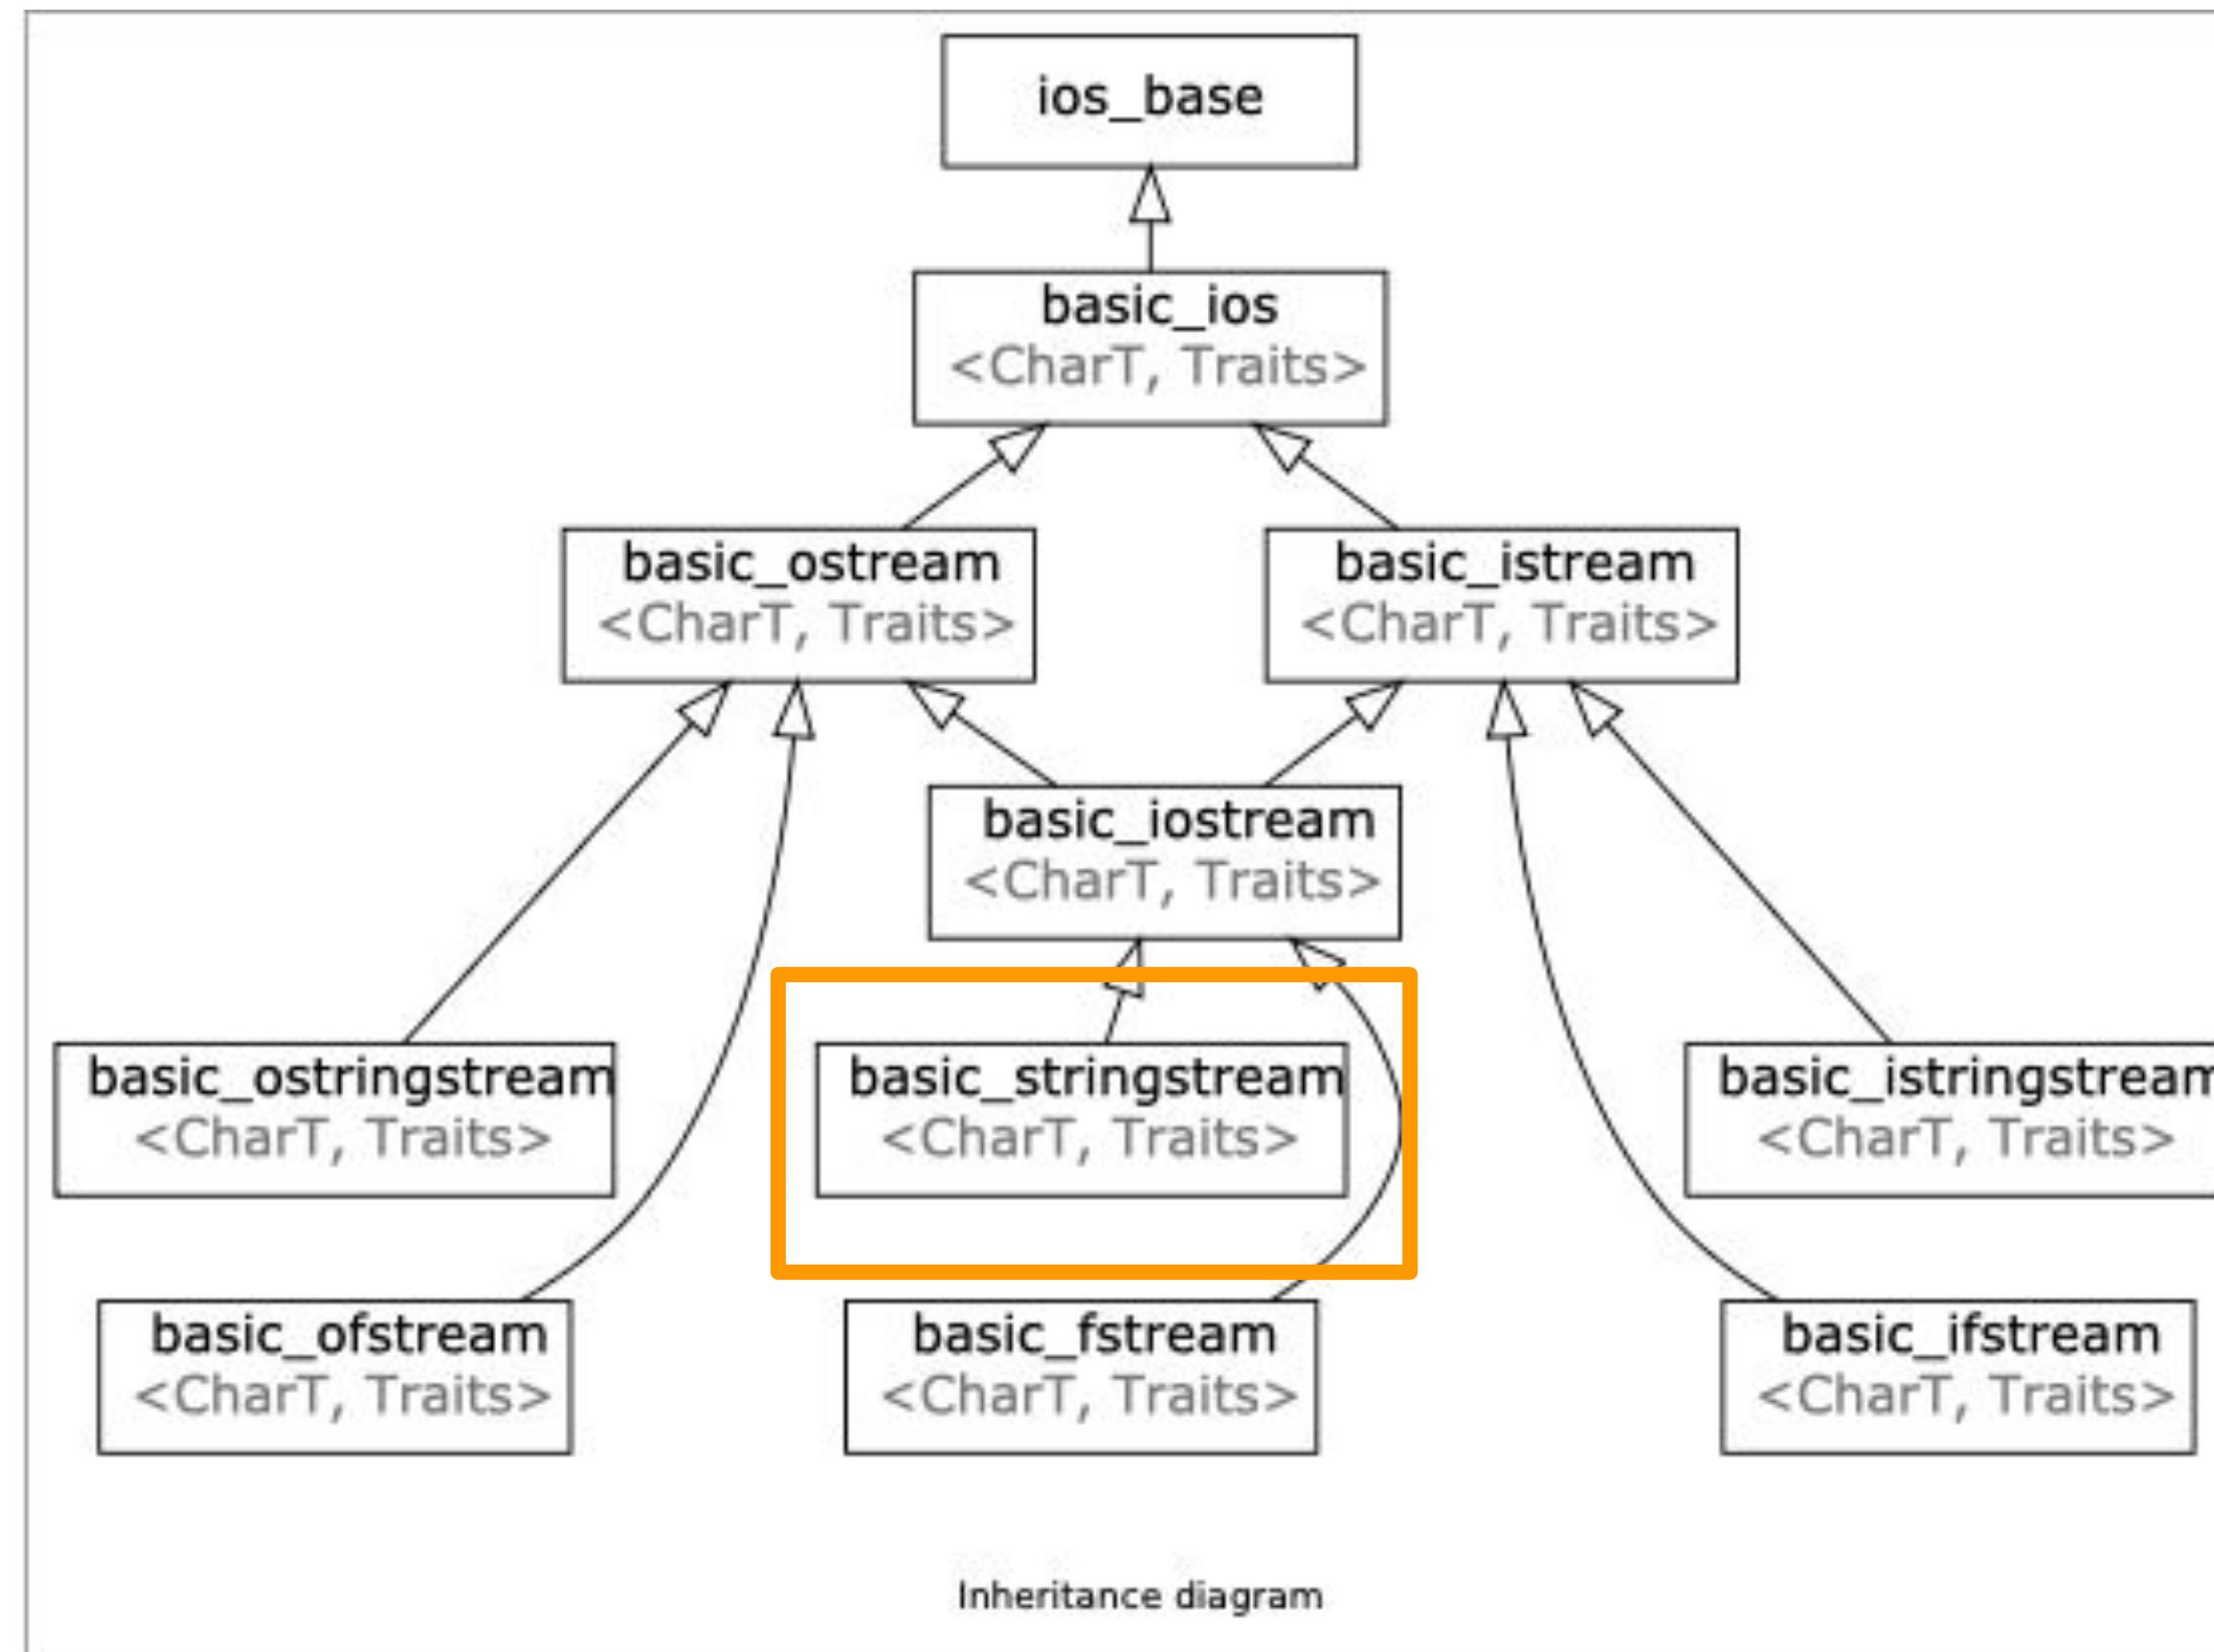

a way to treat strings as streams

Utility?

stringstreams are useful for
use-cases that deal with mixing data
types

What streams actually are

std::stringstream example

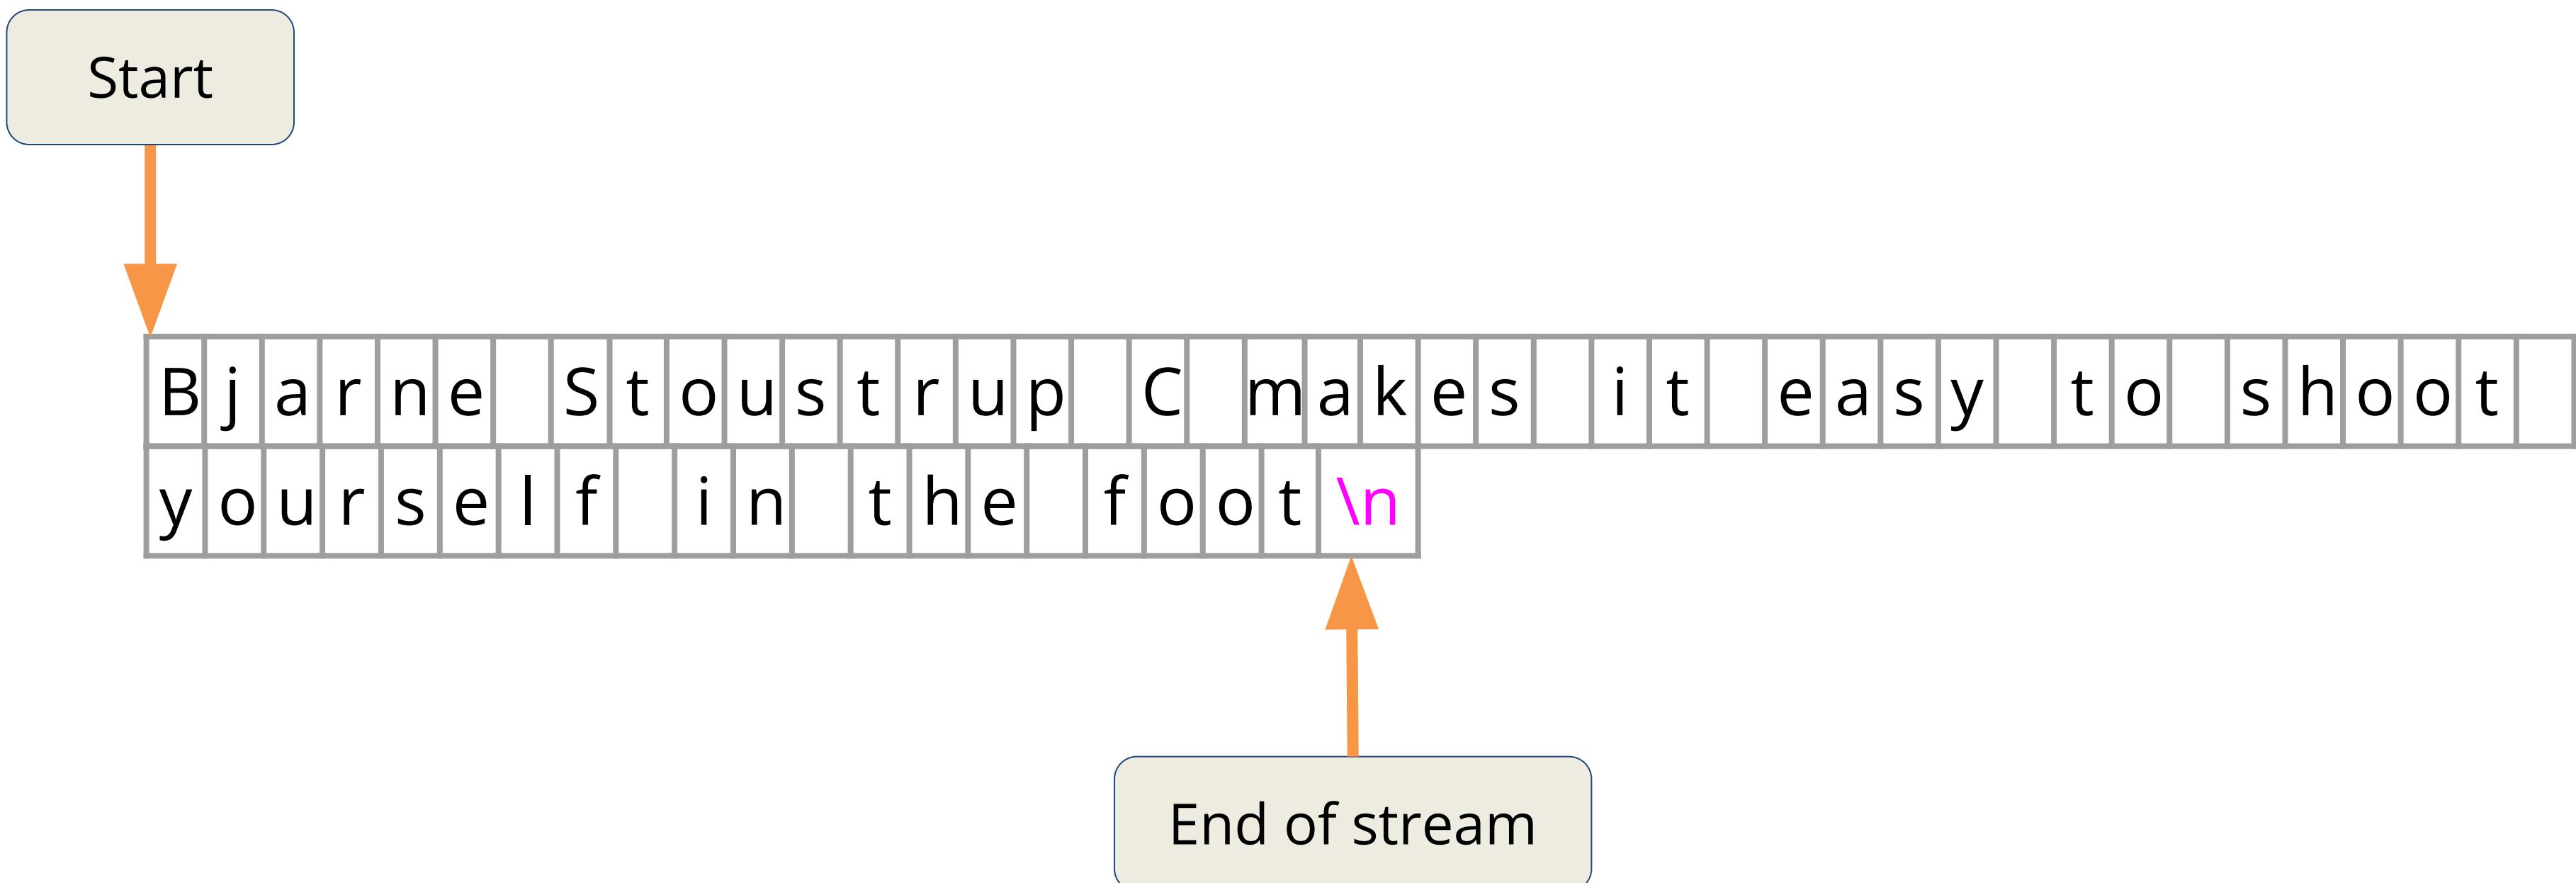

```
void foo() {  
    /// partial Bjarne Quote  
    std::string initial_quote = "Bjarne Stroustrup C makes it easy to shoot  
    yourself in the foot";  
  
    /// create a stringstream  
    std::stringstream ss(initial_quote);  
  
    /// data destinations  
    std::string first;  
    std::string last;  
    std::string language, extracted_quote;  
  
    ss >> first >> last >> language >> extracted_quote;  
    std::cout << first << " " << last << " said this: " << language << " " <<  
    extracted_quote << std::endl;  
}
```

initialize
stringstream with
string constructor

std::stringstream example

```
void foo() {  
    /// partial Bjarne Quote  
    std::string initial_quote = "Bjarne Stroustrup C makes it easy to shoot  
    yourself in the foot";  
  
    /// create a stringstream  
    std::stringstream ss;  
    ss << initial_quote; ← since this is a stream we can  
    // data destinations also insert the  
    std::string first; initial_quote like this!  
    std::string last;  
    std::string language, extracted_quote;  
  
    ss >> first >> last >> language >> extracted_quote;  
    std::cout << first << " " << last << " said this: " << language << " "  
    extracted_quote << std::endl;  
}
```

what the stream looks like!

std::stringstream example

```
void foo() {  
    /// partial Bjarne Quote  
    std::string initial_quote = "Bjarne Stroustrup C makes it easy to shoot  
    yourself in the foot";  
  
    /// create a stringstream  
    std::stringstream ss(initial_quote);  
  
    /// data destinations  
    std::string first;  
    std::string last;  
    std::string language, extracted_quote;  
  
    ss >> first >> last >> language;  
    std::cout << first << " " << last << " said this: " << language << " " <<  
    extracted_quote << std::endl;  
}
```

Remember! Streams
move data from one
place to another

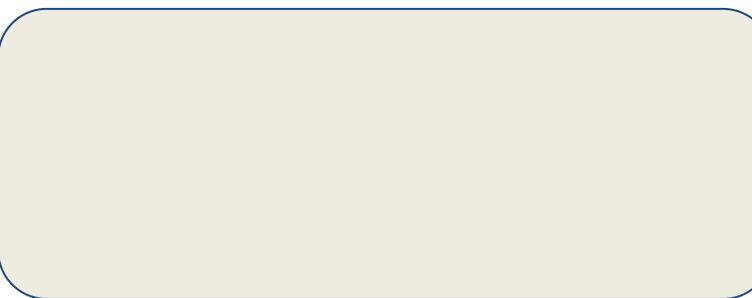

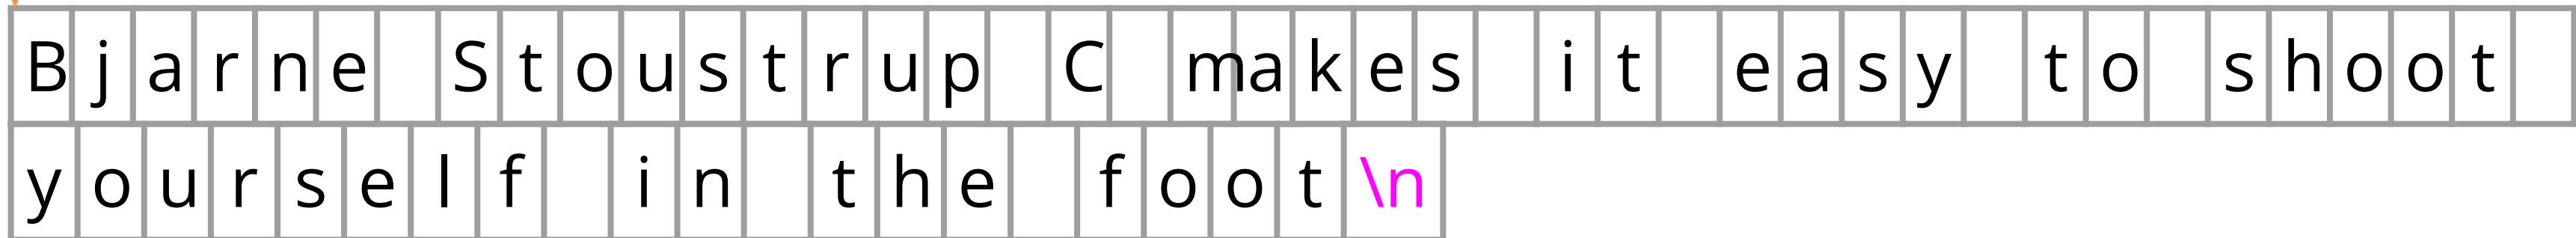

std::stringstream example

```
void foo() {  
    /// partial Bjarne Quote  
    std::string initial_quote = "Bjarne Stroustrup C makes it easy to shoot  
    yourself in the foot";  
  
    /// create a stringstream  
    std::stringstream ss(initial_quote);  
  
    /// data destinations  
    std::string first;  
    std::string last;  
    std::string language, extracted_quote;  
  
    ss >> first >> last >> language;  
    std::cout << first << " " << last << " said this: " << language << " " <<  
    extracted_quote << std::endl;  
}
```

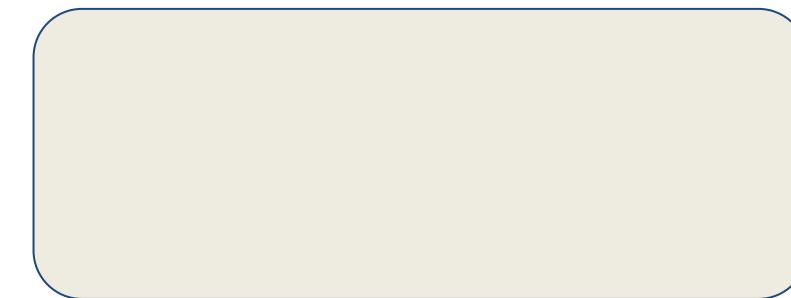

We're making use of the insertion operator

what the stream looks like!

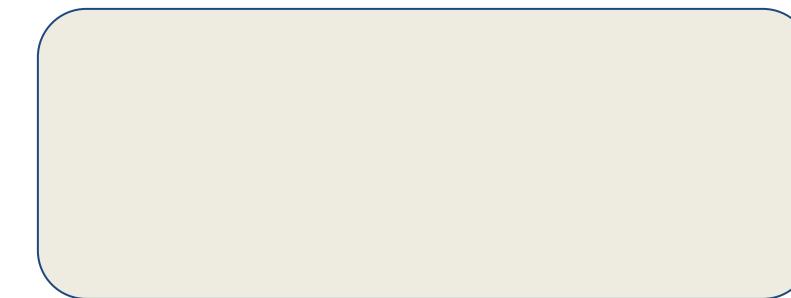

```
ss >> first >> last >> language;
```

First

Last

Language

what the stream looks like!

```
ss >> first >> last >> language;
```

extracts from the stream!

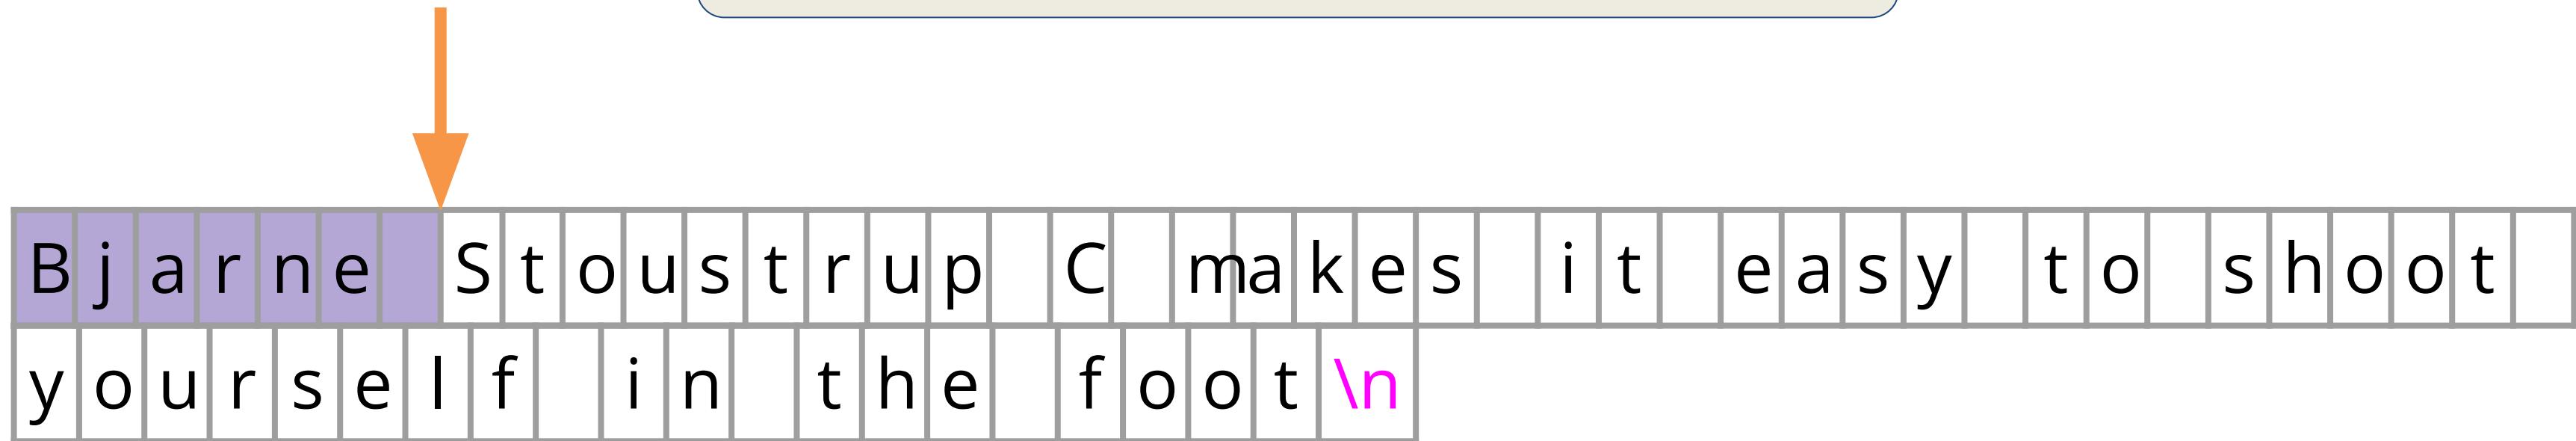

First

Last

Language

what the stream looks like!

```
ss >> first >> last >> language;
```

Bjarne

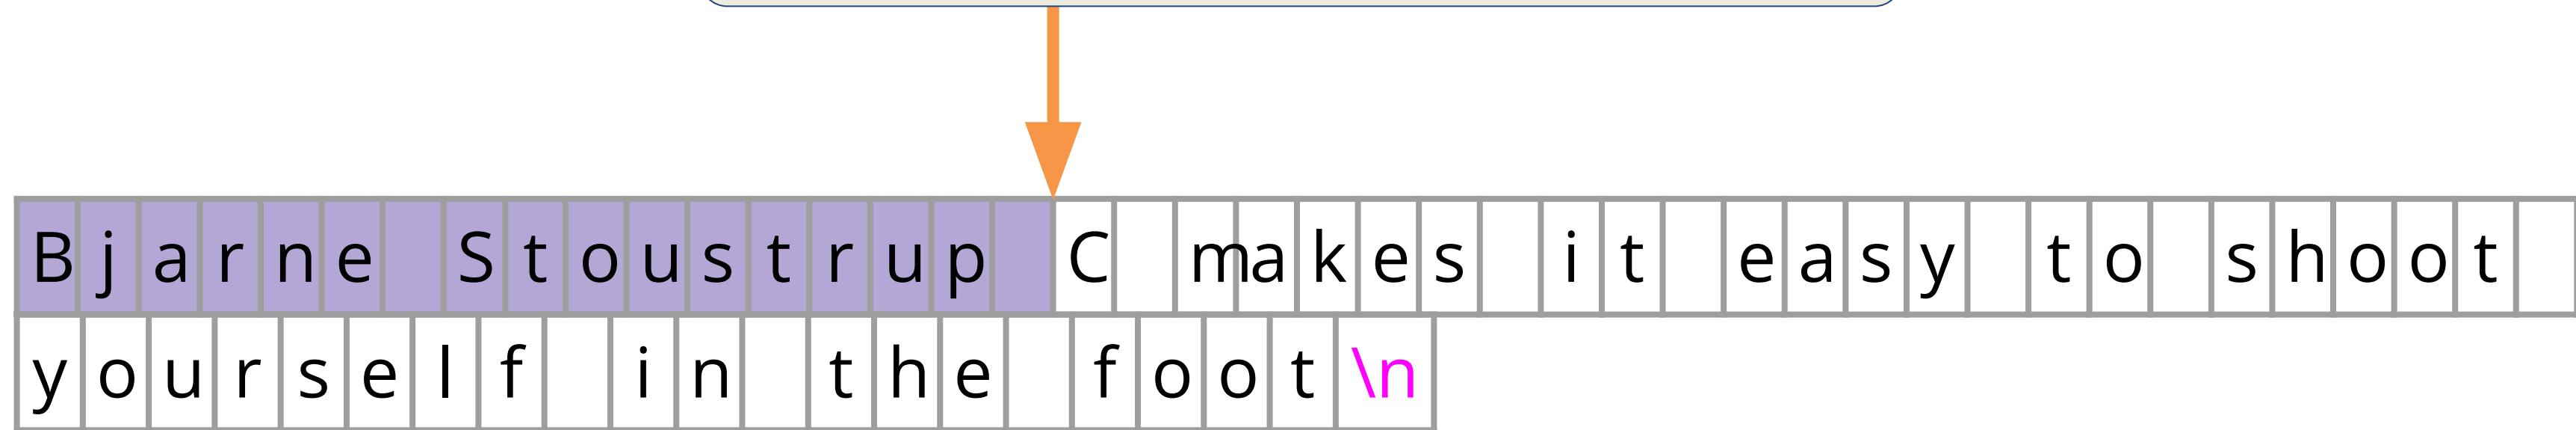

First

Last

Language

what the stream looks like!

```
ss >> first >> last >> language;
```

Stroustrup

Last

C

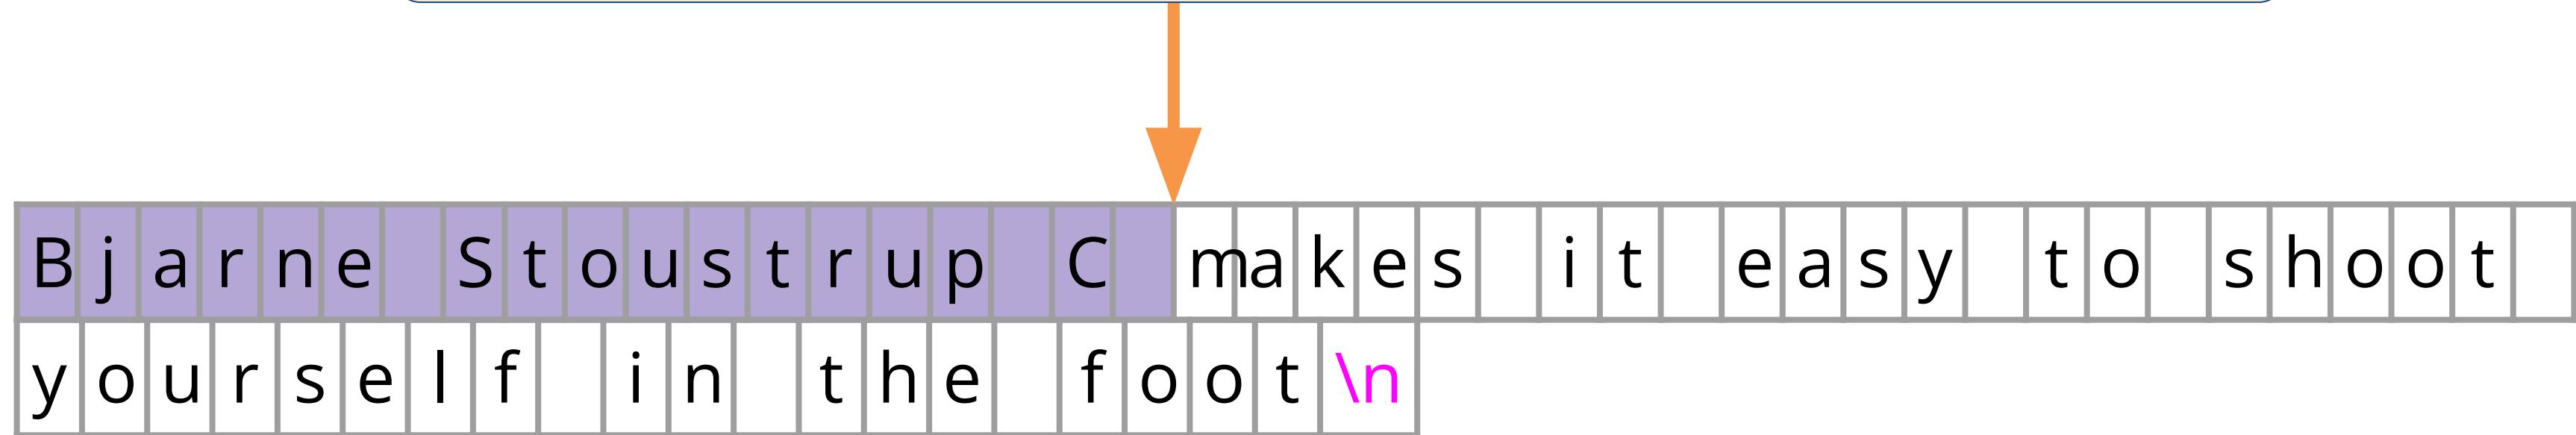

Language

std::stringstream example

```
void foo() {  
    /// partial Bjarne Quote  
    std::string initial_quote = "Bjarne Stroustrup C makes it easy to shoot  
    yourself in the foot";  
  
    /// create a stringstream  
    std::stringstream ss(initial_quote);  
  
    /// data destinations  
    std::string first;  
    std::string last;  
    std::string language, extracted_quote; ← We want to extract the quote!  
  
    ss >> first >> last >> language;  
    std::cout << first << " " << last << " said this: " << language << " " <<  
    extracted_quote << std::endl;  
}
```

what the stream looks like!

```
ss >> first >> last >> language >> extracted_quote;
```

Bjarne

Stroustrup

C

First

Last

Language

what the stream looks like!

Problem:

?

```
ss >> first >> last >> language >> extracted_quote;
```

Bjarne

Stroustrup

C

First

Last

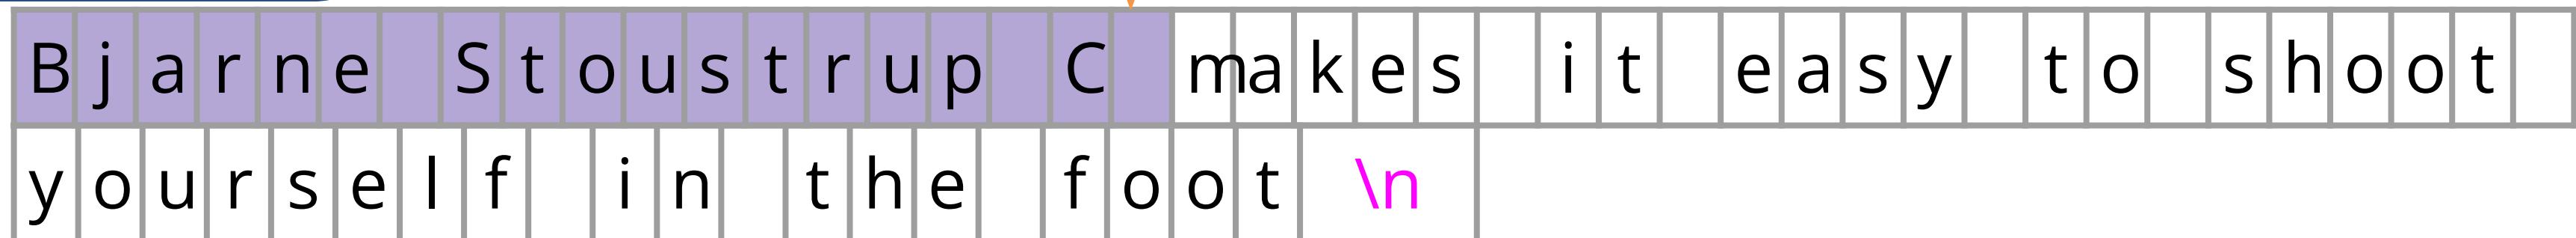

Language

what the stream looks like!

Problem:

The `>>` operator only reads until the next whitespace!

```
ss >> first >> last >> language >> extracted_quote;
```

Bjarne

Stroustrup

C

First

Last

Language

what the stream looks like!

Problem:

The `>>` operator only reads until the next whitespace!

```
ss >> first >> last >> language >> extracted_quote;
```

Bjarne

Stroustrup

C

First

Last

Language

Use `getline()`!

```
istream& getline(istream& is, string& str, char delim)
```

- `getline()` reads an input stream, `is`, up until the `delim` char and stores it in some buffer, `str`.

Use `getline()`!

```
istream& getline(istream& is, string& str, char delim)
```

- `getline()` reads an input stream, `is`, up until the `delim` char and stores it in some buffer, `str`.
- The `delim` char is by default '`\n`'.

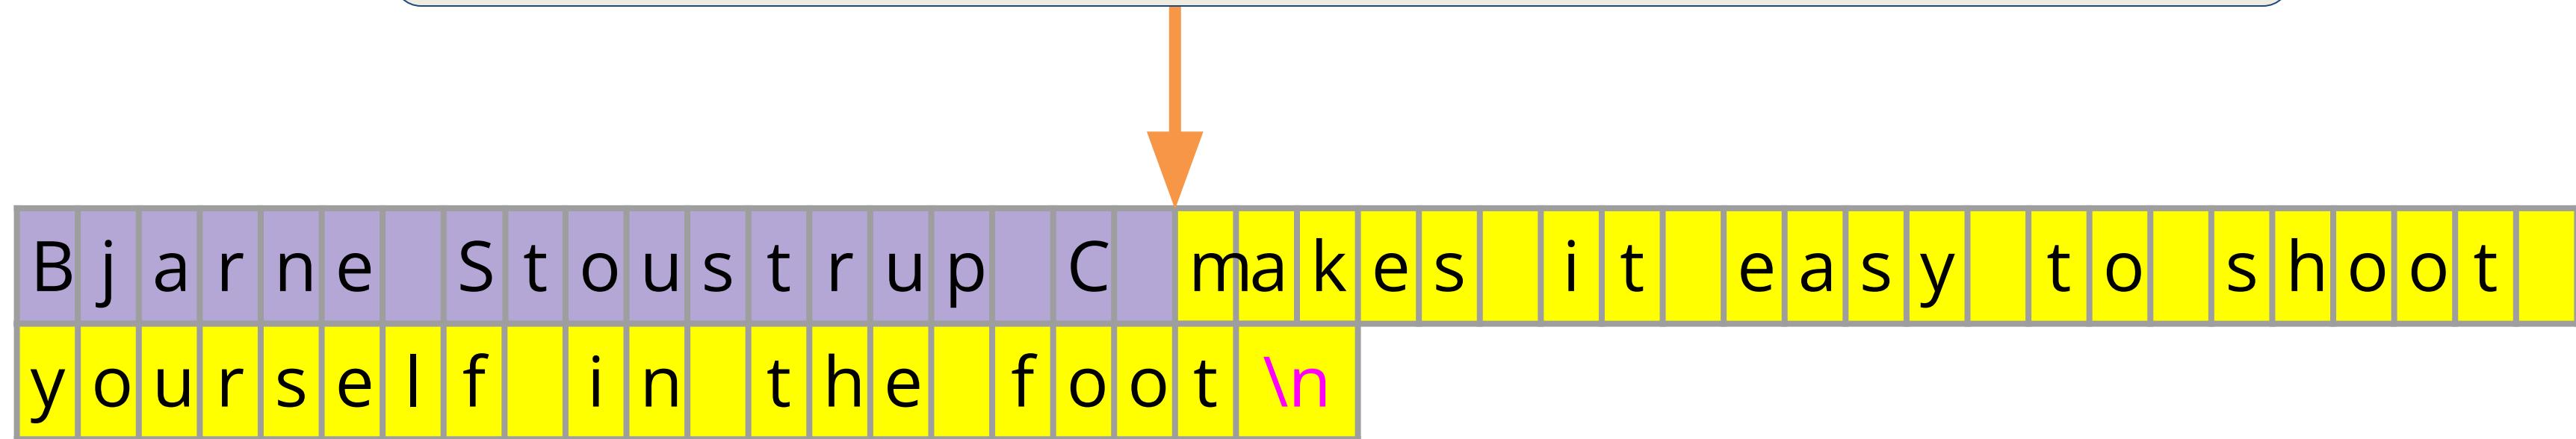

Use getline() !

istream& getline(istream& is, string& str, char delim)

- **getline()** reads an input stream, **is**, up until the **delim** char and stores it in some buffer, **str**.
- The **delim** char is by default ‘\n’.
- **getline()** ***consumes*** the **delim** character!
 - PAY ATTENTION TO THIS :)

use std::getline()!

```
ss >> first >> last >> language >> extracted_quote;
```

Bjarne

First

Stroustrup

Last

C

Language

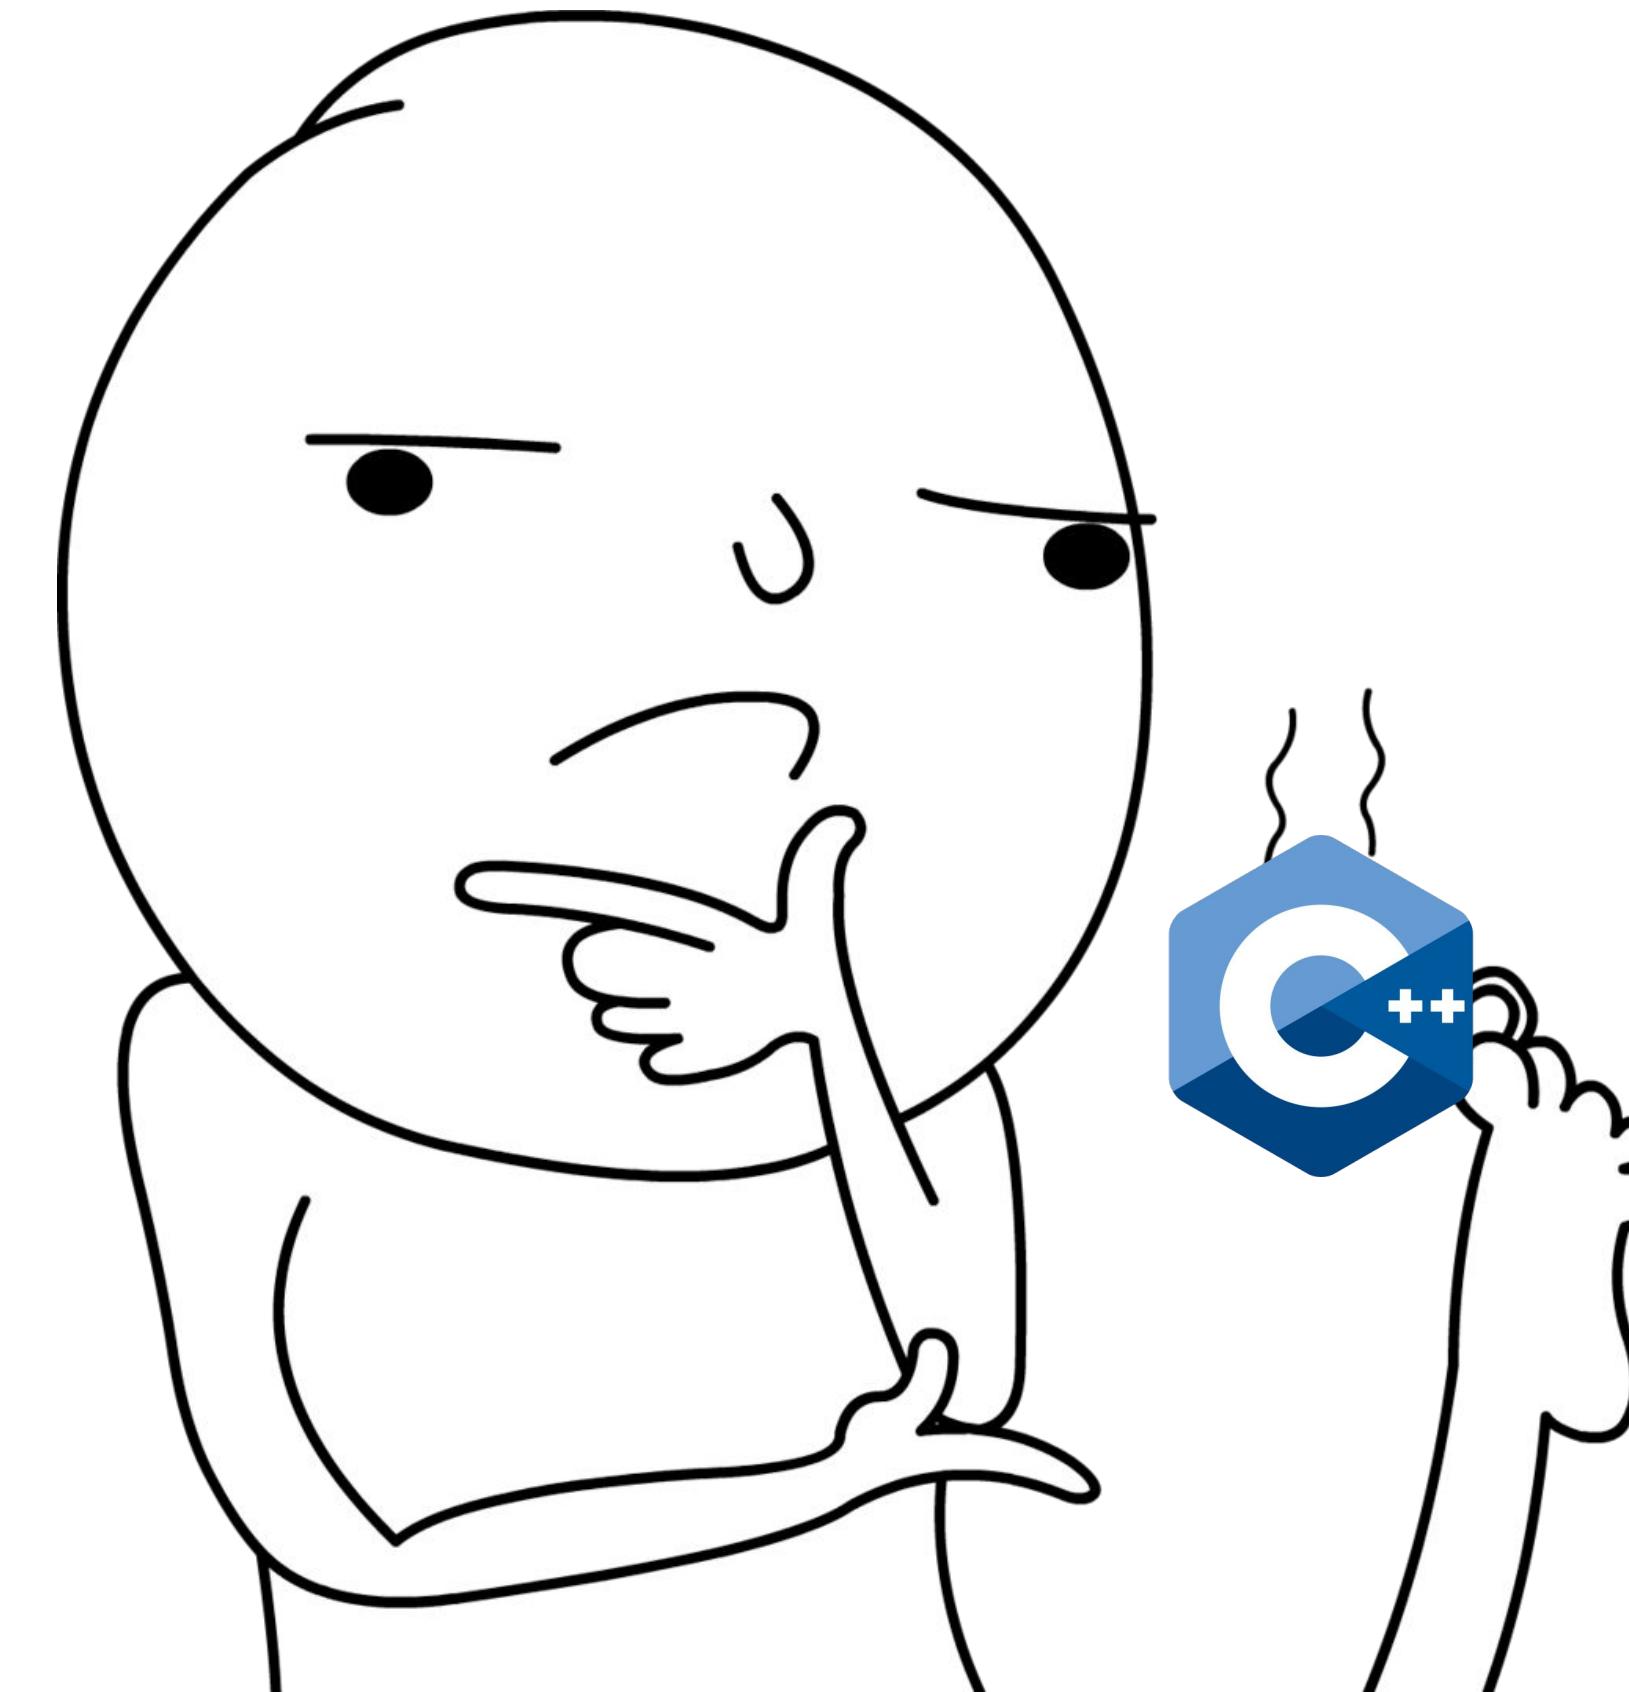

std::stringstream example

```
void foo() {
    /// partial Bjarne Quote
    std::string initial_quote = "Bjarne Stroustrup C makes it easy to shoot
    yourself in the foot";

    /// create a stringstream
    std::stringstream ss(initial_quote);

    /// data destinations
    std::string first;
    std::string last;
    std::string language, extracted_quote;
    ss >> first >> last >> language;
    std::getline(ss, extracted_quote);
    std::cout << first << " " << last << " said this: '" << language << " "
    extracted_quote + "'" << std::endl;
}
```

What questions do we have?

Plan

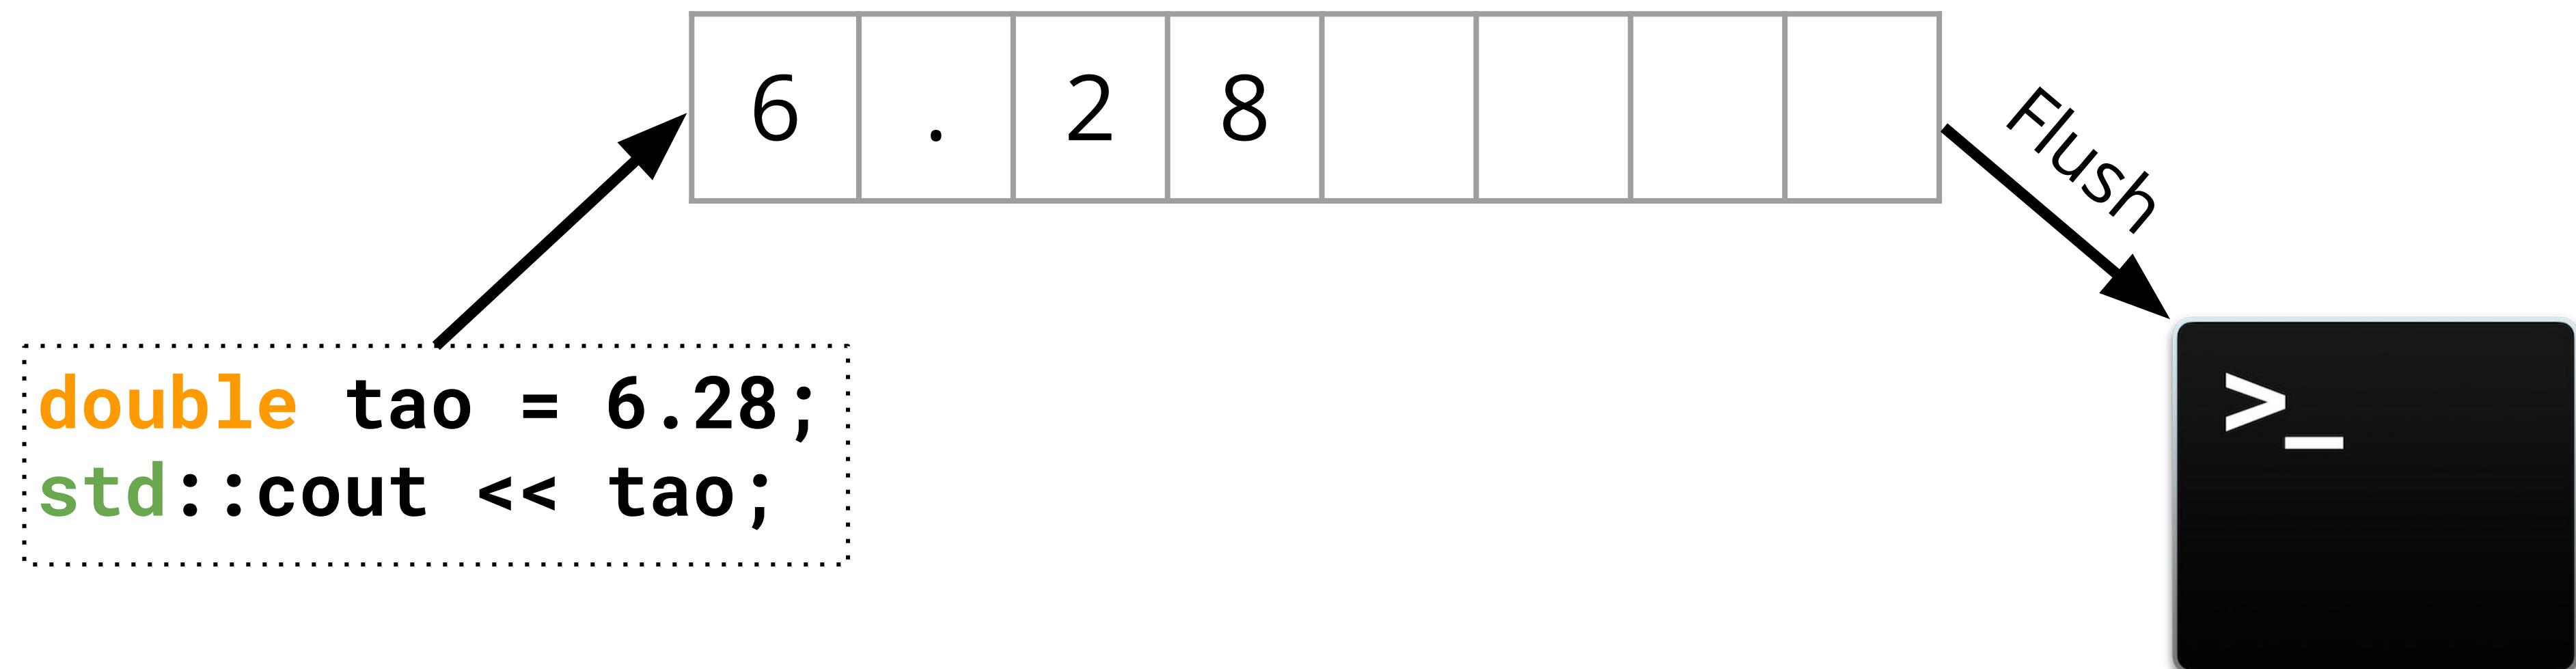

1. Quick recap
2. What are streams??!!
3. `stringstream`!
4. **cout and cin**
5. Output streams
6. Input streams

Output Streams

- a way to write data to a destination/external source
 - ex. writing out something to the console (`std::cout`)
 - use the `<<` operator to **send** to the output stream

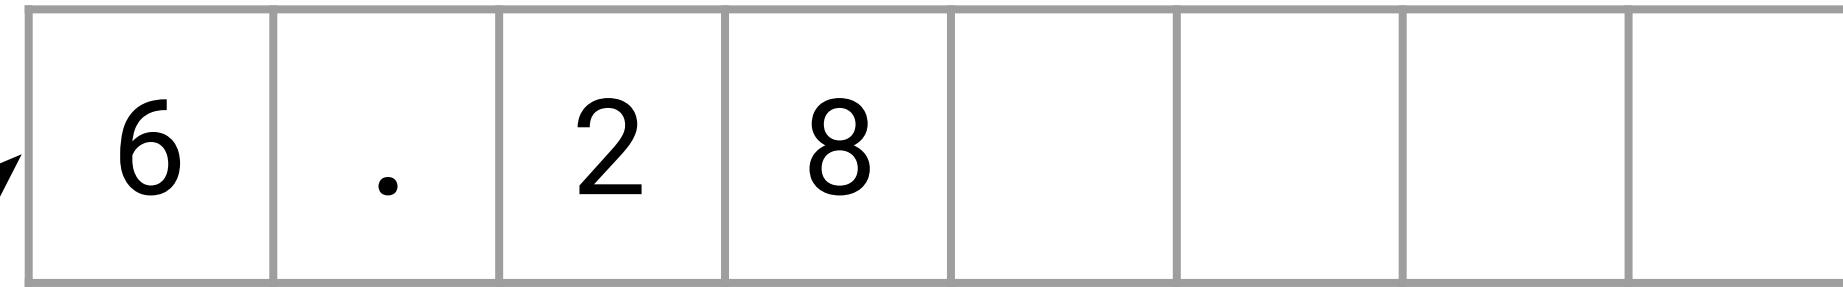

Zooming in on Output Streams!

Character in output streams are stored in an intermediary buffer before being flushed to the destination

Zooming in on Output Streams!

```
double tao = 6.28;  
std::cout << tao;
```

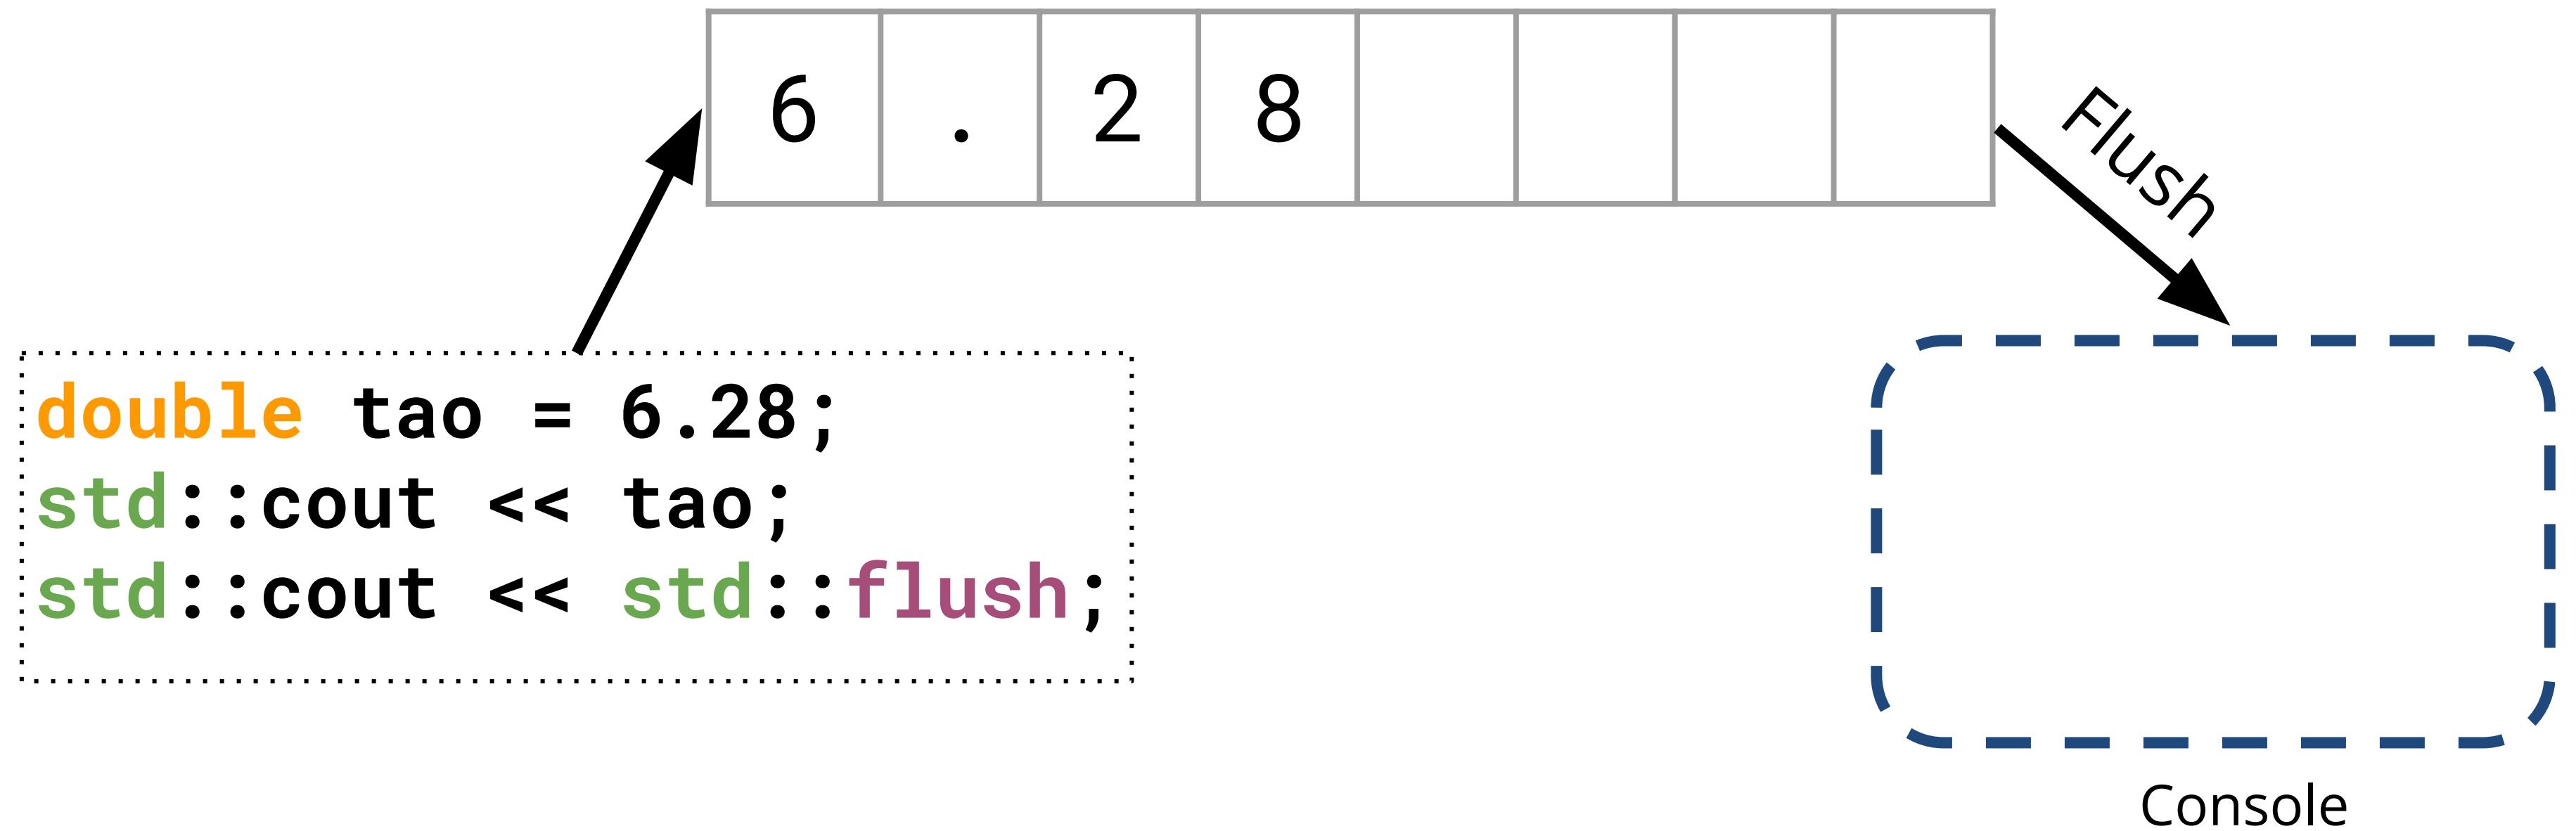

Flush

>_

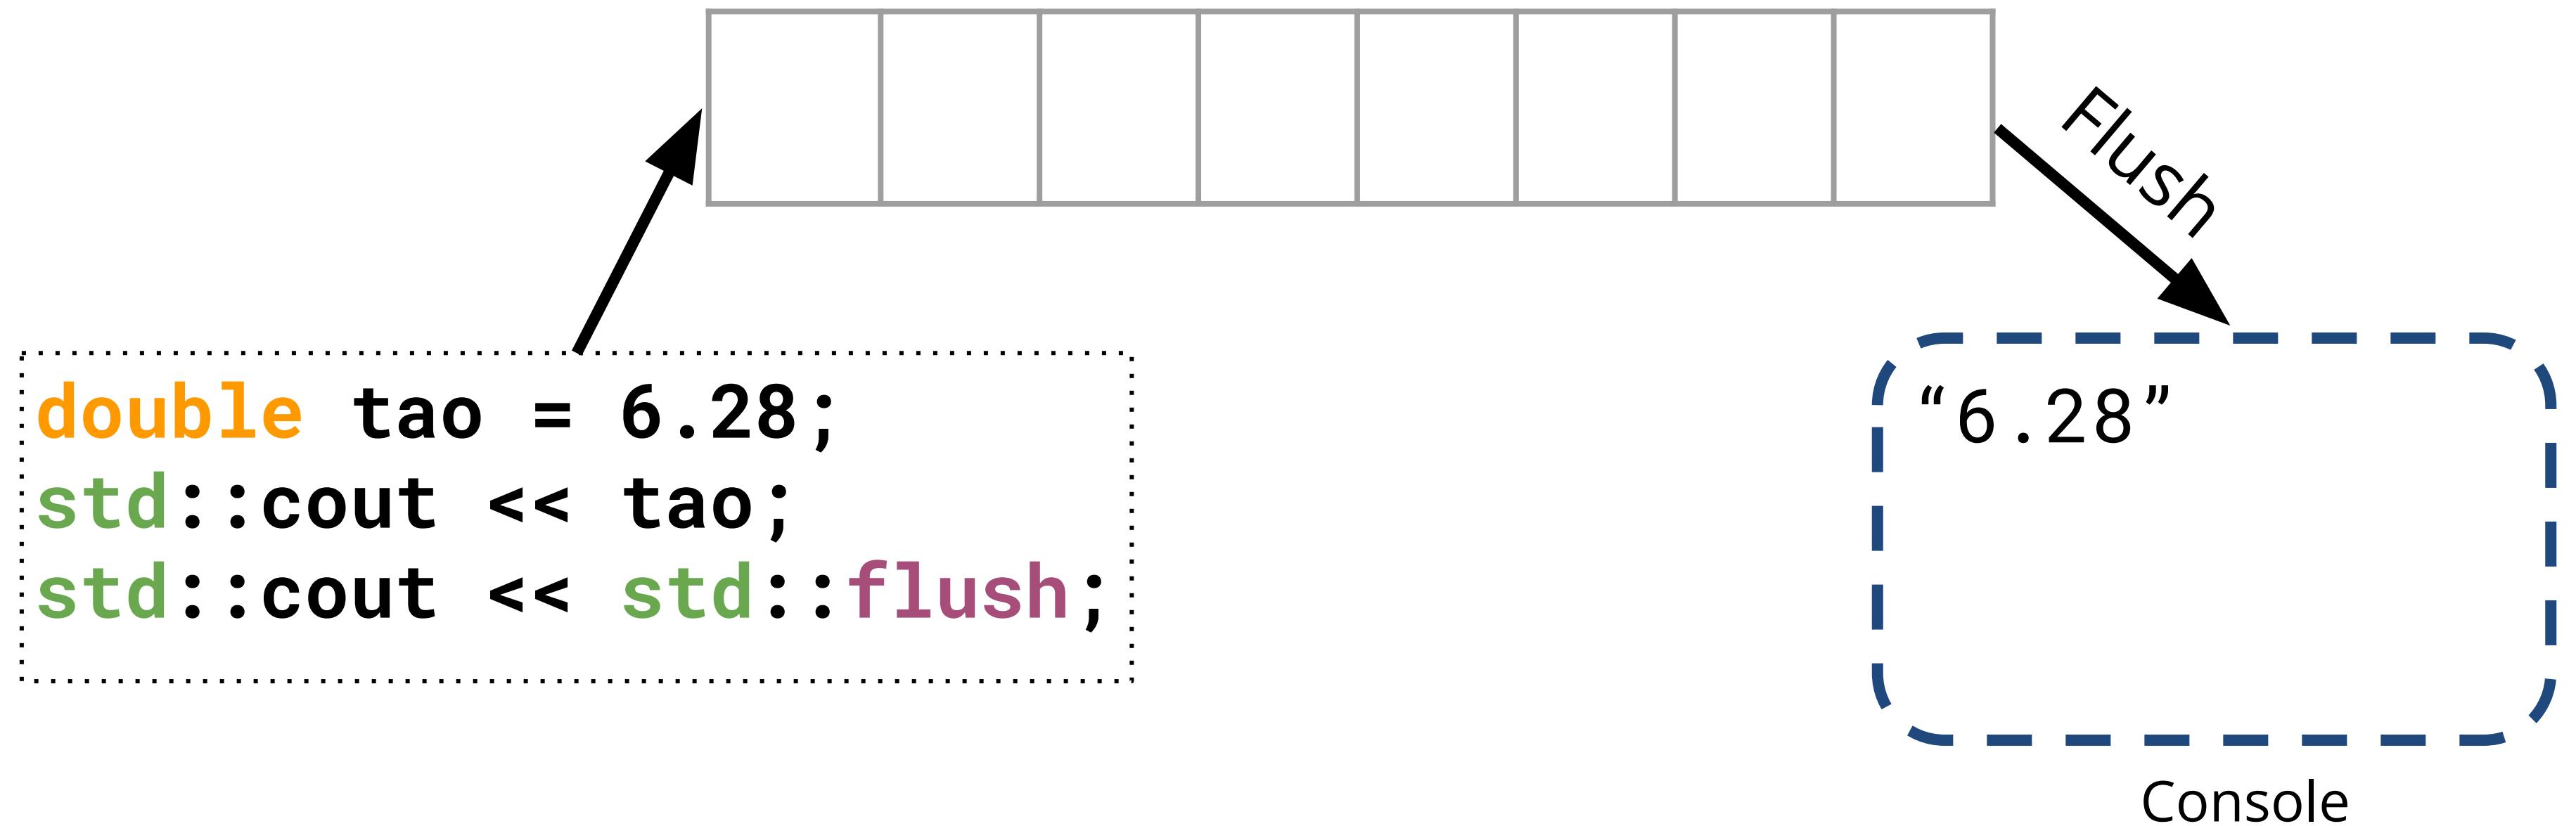

std::cout stream is
line-buffered

contents in buffer not
shown on external source
until an explicit flush
occurs!

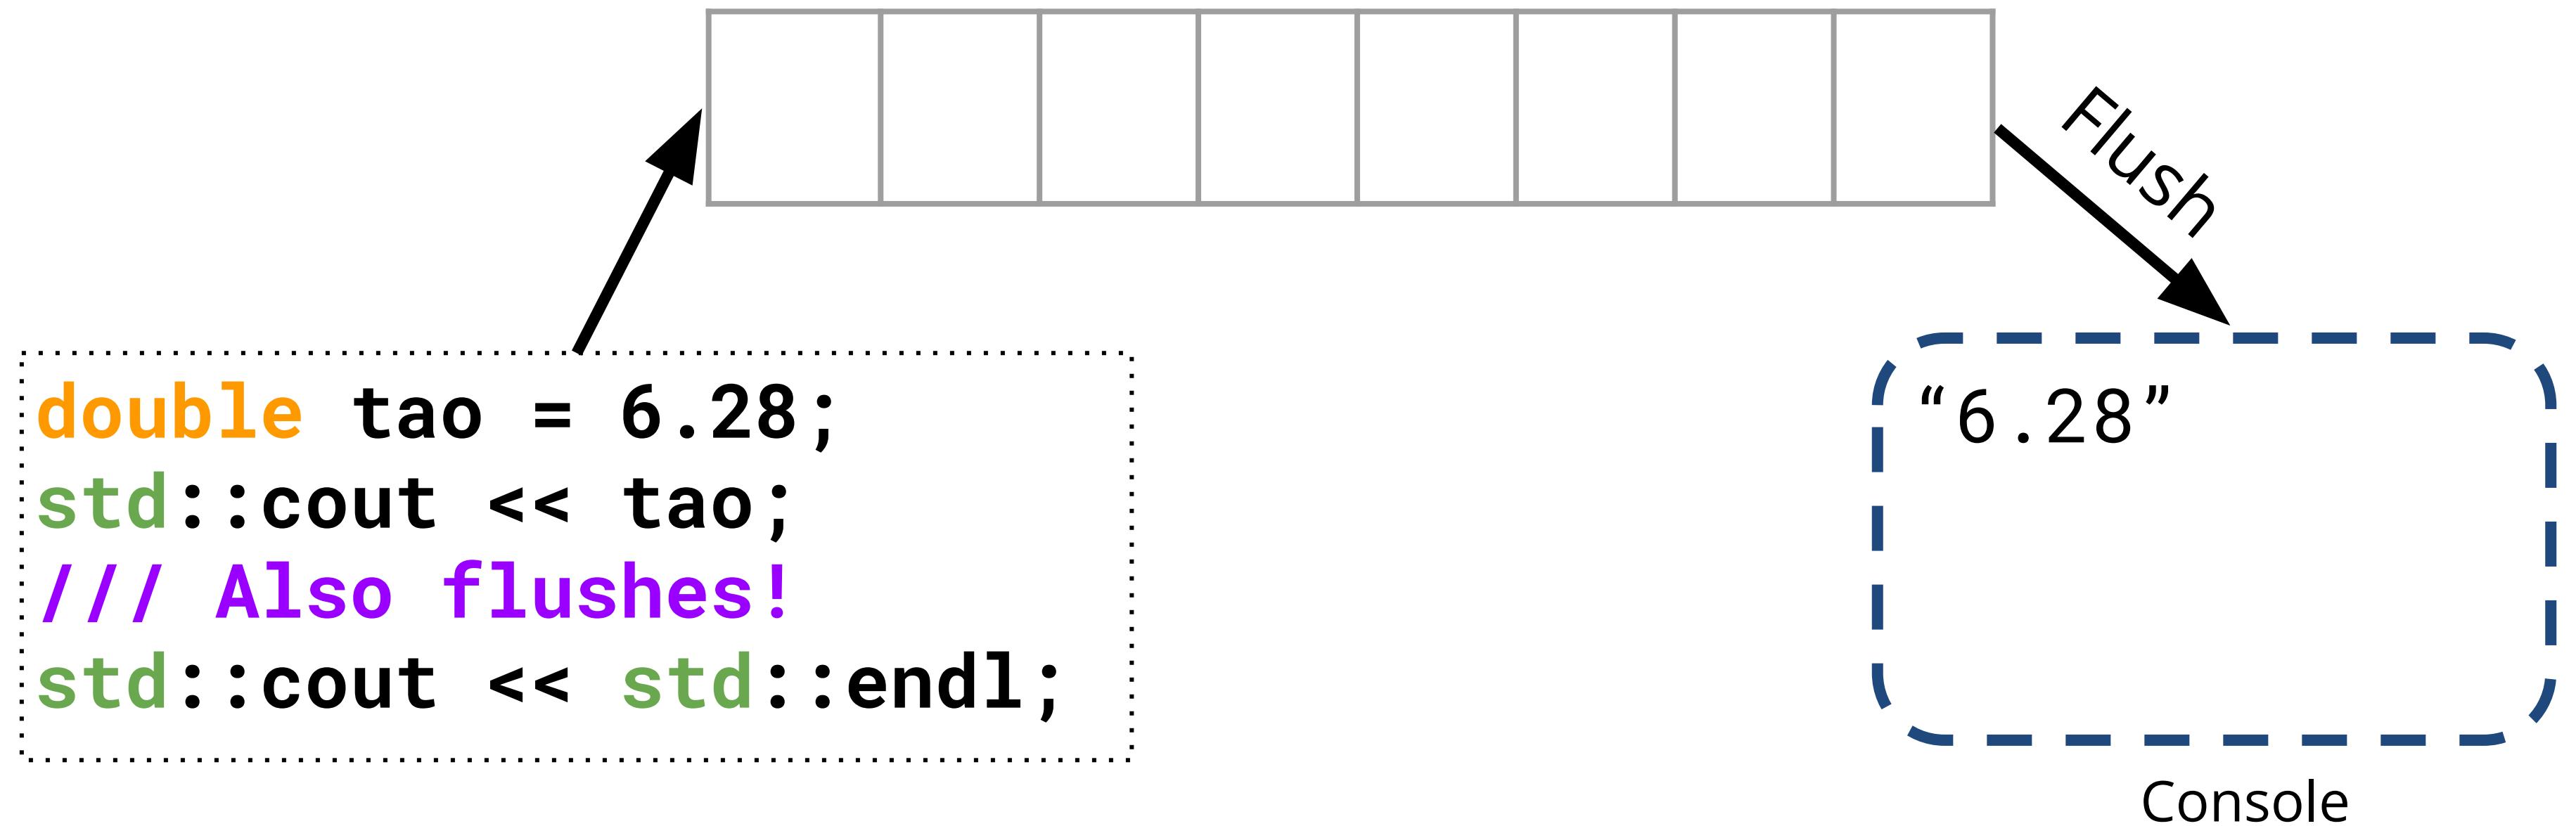

Zooming in on Output Streams!

Zooming in on Output Streams!

Zooming in on Output Streams!

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

Output:

“1”
“2”
“3”
“4”
“5”

std::endl tells the cout stream to end the line!

Here's without std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i;
    }
    return 0;
}
```

Output:

“12345”

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

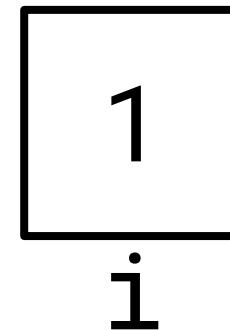

Output:

“1”
“2”
“3”
“4”
“5”

std::endl also tells the stream to **flush**

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

intermediate buffer

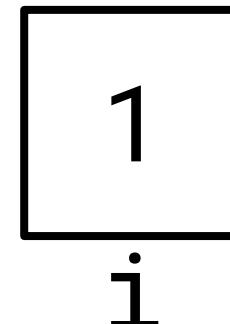

Output:

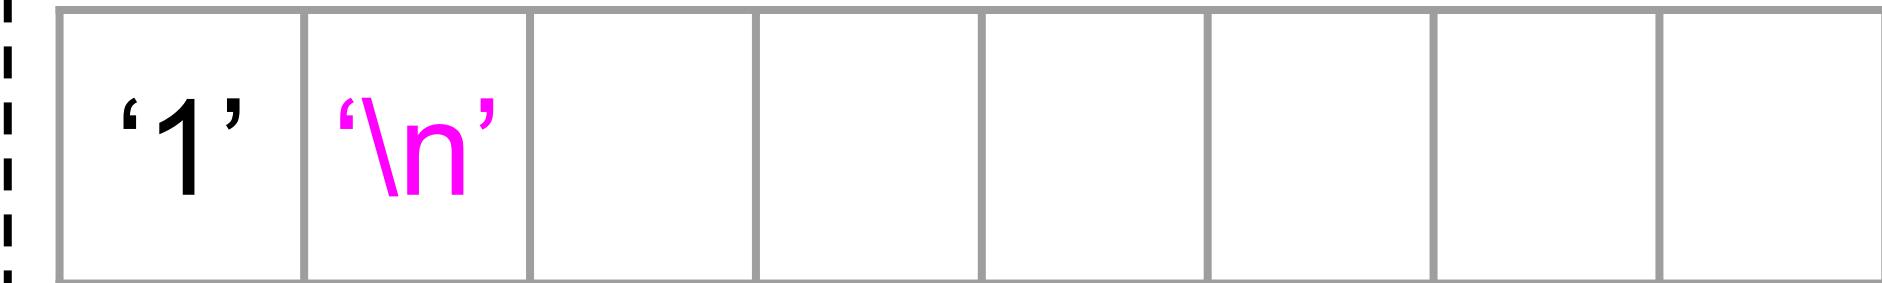

std::endl also tells the stream to **flush**

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

intermediate buffer

endl also flushes! So it is
immediately sent to
destination

Output:

std::endl also tells the
stream to **flush**

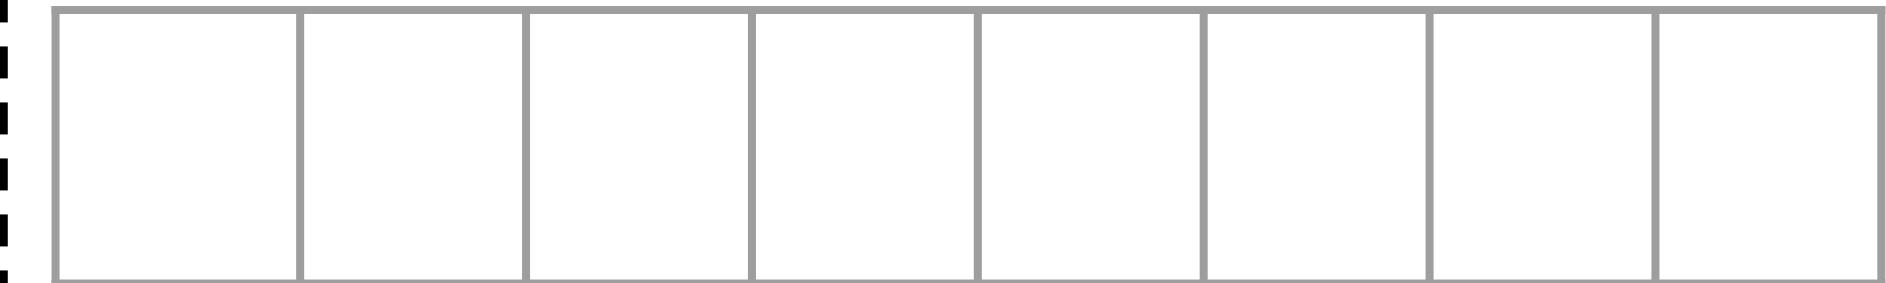

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

2
i

std::endl also tells the stream to **flush**

intermediate buffer

When a stream is flushed
the **intermediate buffer**
is cleared!

“ 1 ”

Output:

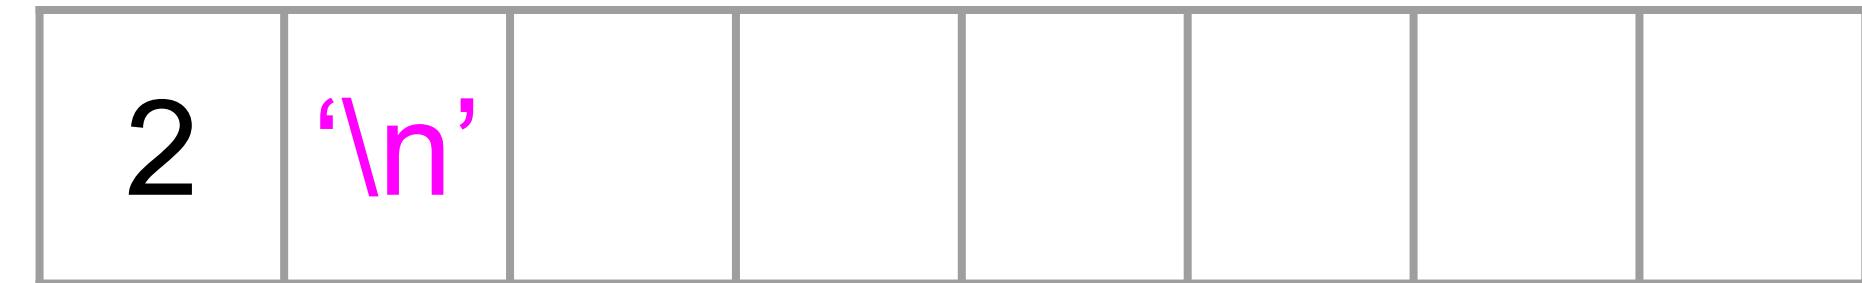

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

2
i

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

“ 1 ”

Output:

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

3
i

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

Output:

“1”
“2”

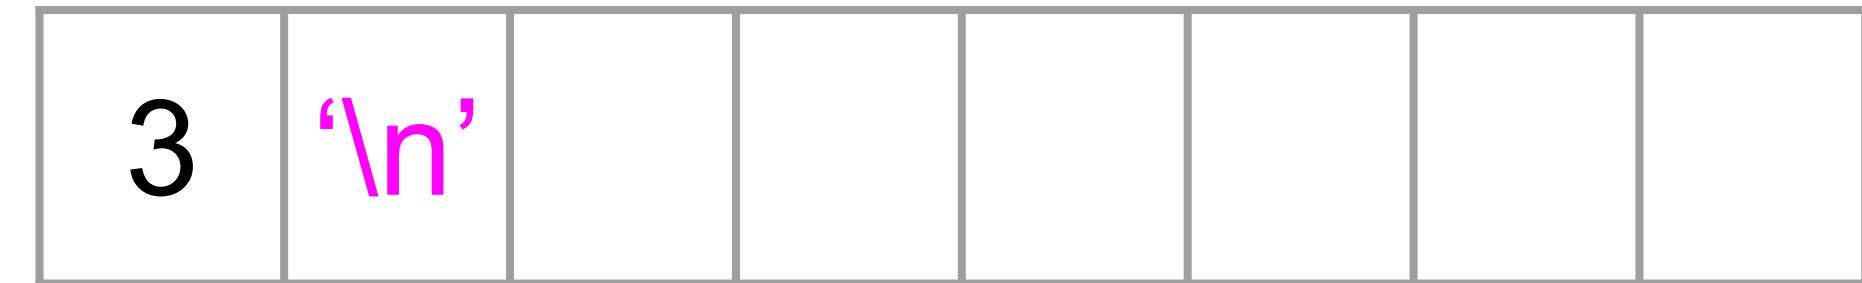

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

3
i

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

Output:

“1”
“2”

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

4
i

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

Output:

“1”
“2”
“3”

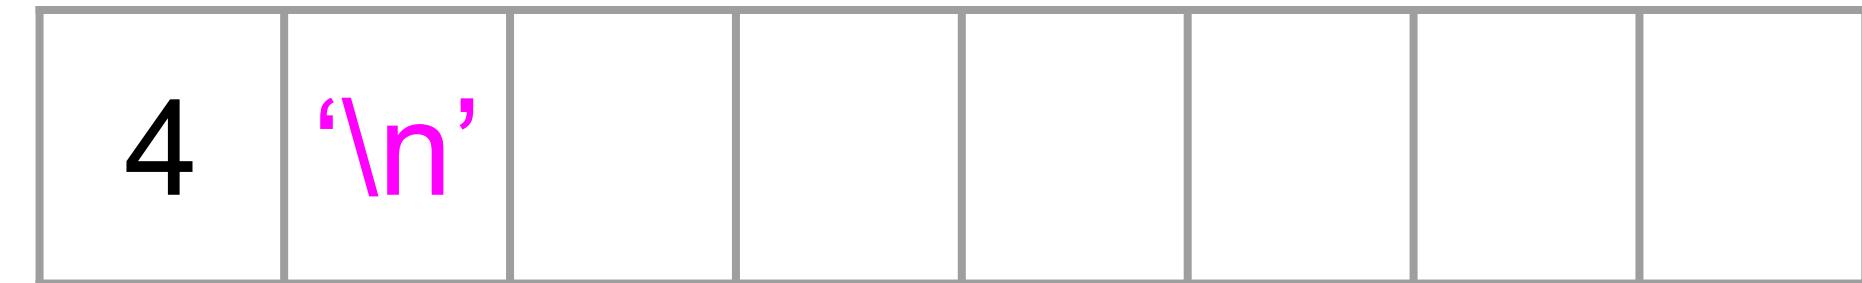

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

4
i

std::endl also tells the stream to **flush**

intermediate buffer

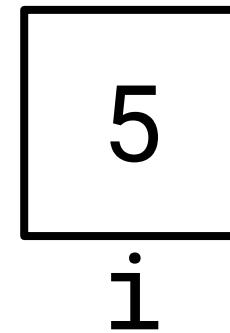

Next integer is put into the stream and immediately flushed!

Output:

“1”
“2”
“3”

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

Output:

“1”

“2”

“3”

“4”

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

5
i

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

Output:

“1”
“2”
“3”
“4”

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

5
i

std::endl also tells the stream to **flush**

intermediate buffer

Next integer is put into the stream and immediately flushed!

Output:

“1”
“2”
“3”
“4”
“5”

std::endl

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << std::endl;
    }
    return 0;
}
```

5
i

std::endl also tells the stream to **flush**

intermediate buffer

flushing is an expensive operation!

Output:

“1”
“2”
“3”
“4”
“5”

' \n '

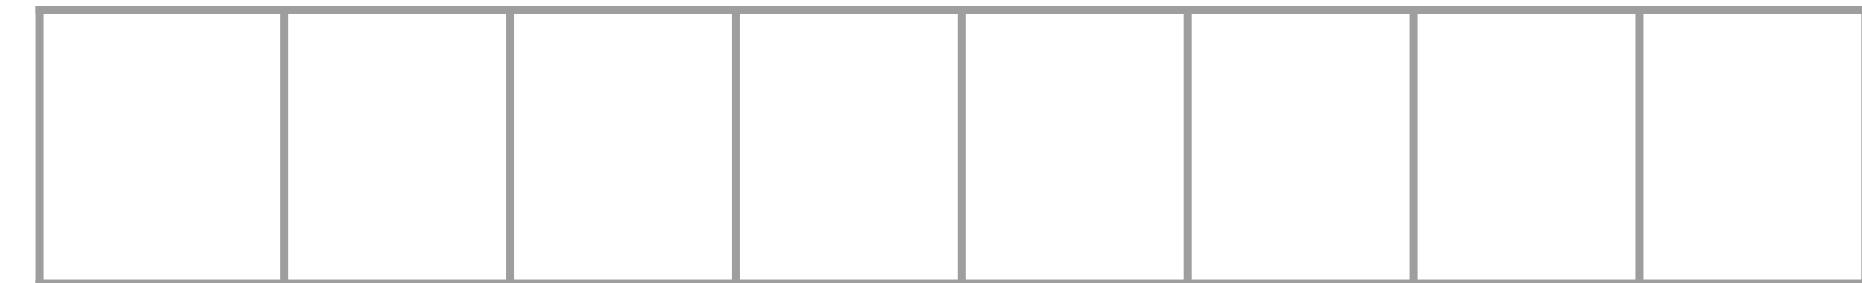

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

1
i

Let's try just adding the
'\n' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

1
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

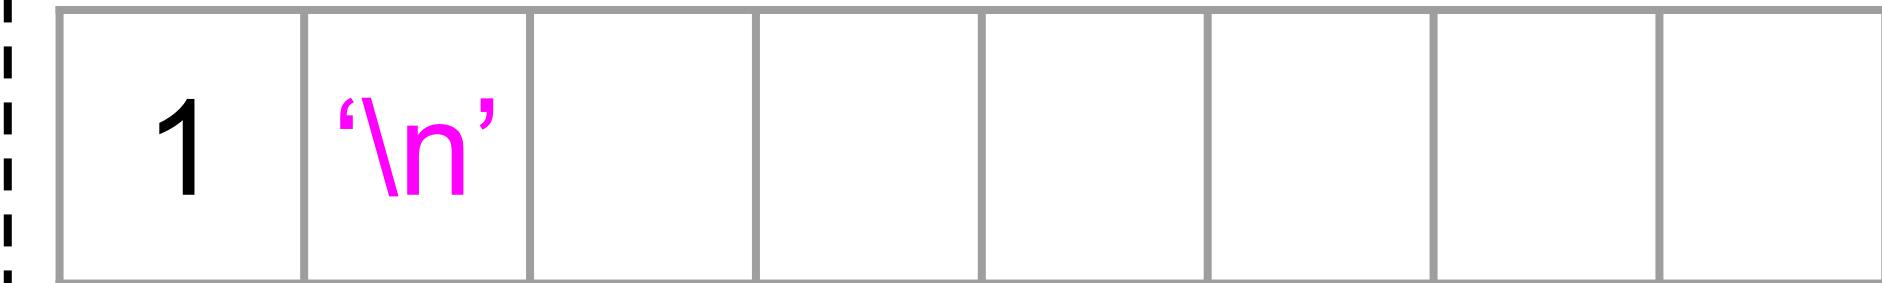

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

2
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

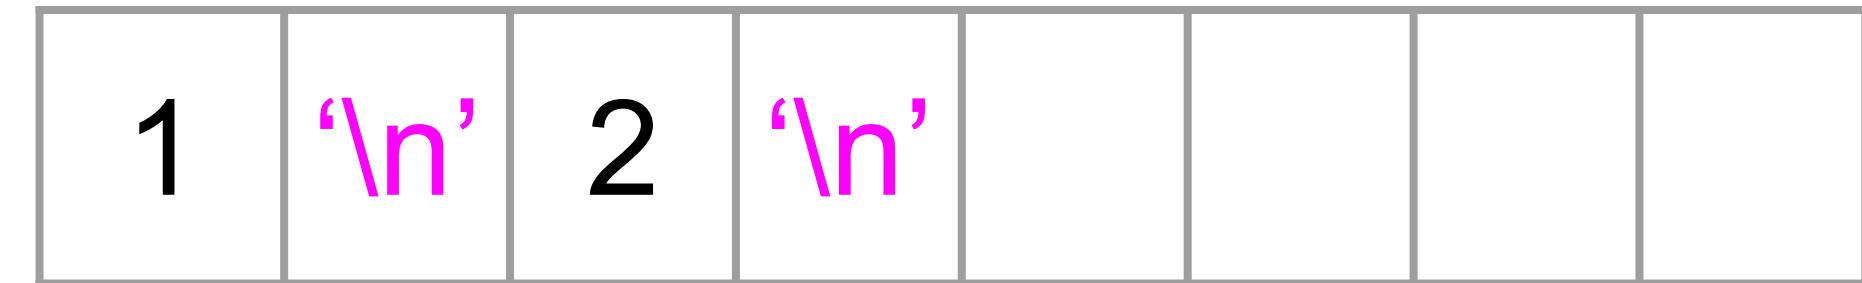

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

2
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

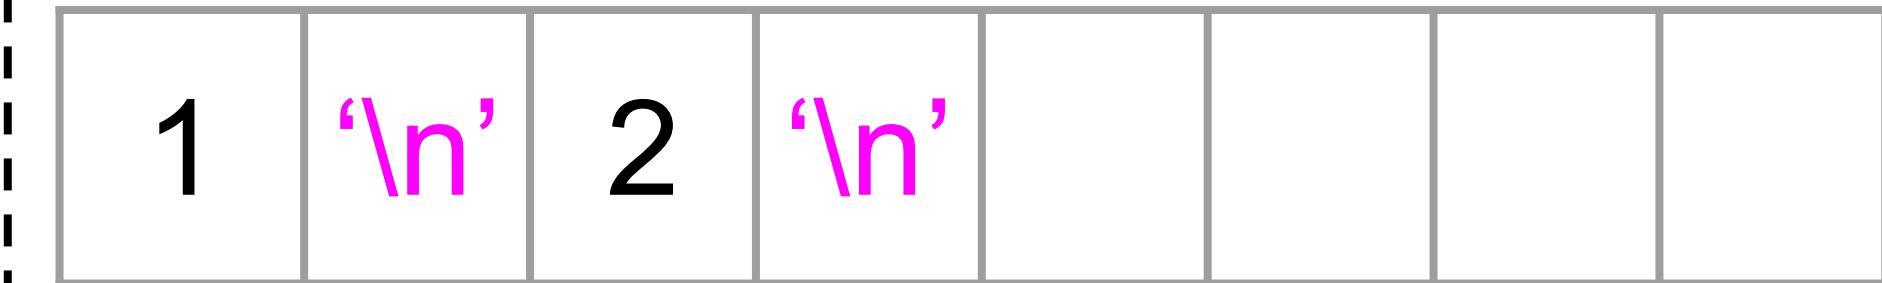

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

3
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

3
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

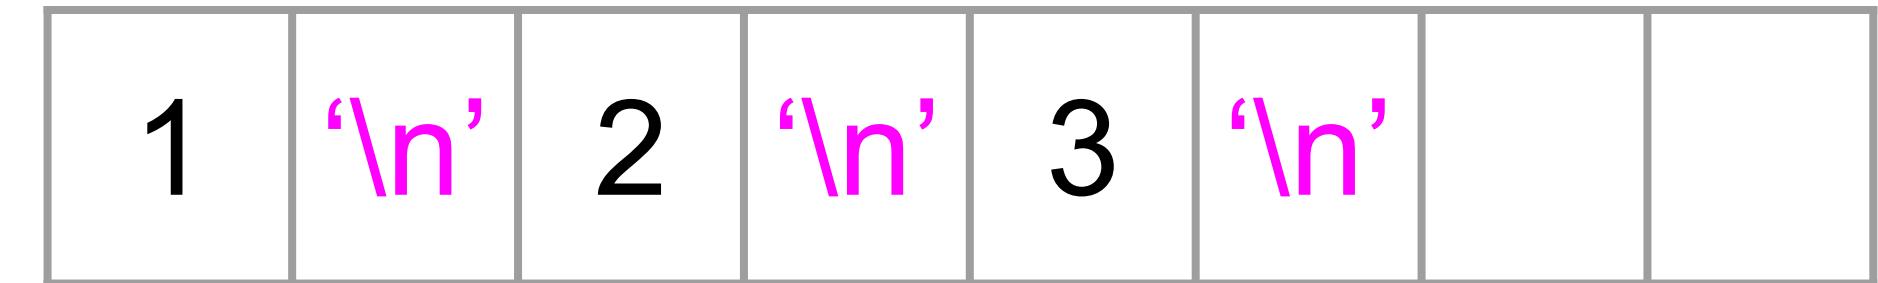

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

4
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

4
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

5
i

Let's try just adding the
' \n ' character

intermediate buffer

C++ is (kinda)
smart! It knows
when to auto flush

Output:

' \n '

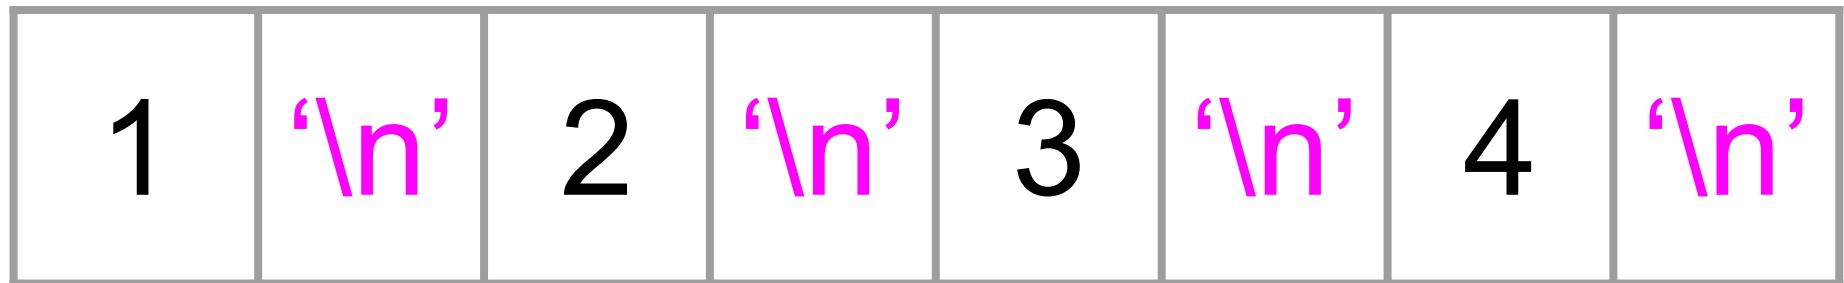

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

5
i

Let's try just adding the
' \n ' character

intermediate buffer

😱😱 Our
intermediate buffer
is full!

Output:

' \n '

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

5
i

Let's try just adding the
' \n ' character

intermediate buffer

C++: FLUSH

Output:

"1"
"2"
"3"
"4"

' \n '

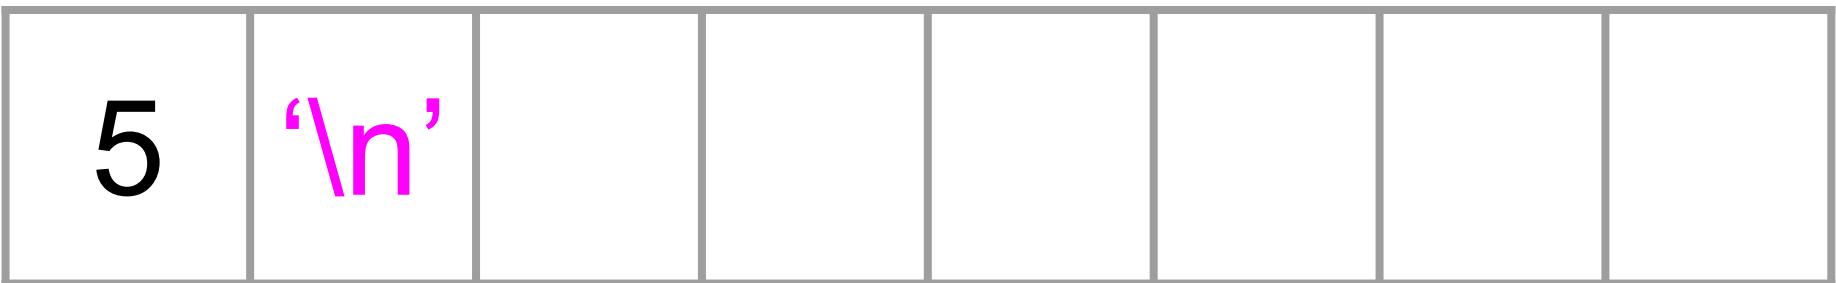

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

5
i

Let's try just adding the
' \n ' character

intermediate buffer

Yay!

Output:

"1"
"2"
"3"
"4"

' \n '

```
int main()
{
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

5
i

Let's try just adding the
' \n ' character

intermediate buffer

Yay!

Output:

"1"

"2"

"3"

"4"

"5"

Recall

- **cerr** and **clog**

cerr: used to output errors (unbuffered)

clog: used for non-critical event logging

(buffered)

read more here: [GeeksForGeeks](#)

A shoutout and clarification

So there's a small caveat to this

A shoutout and clarification

However, upon testing these examples, I observed that '\n' seems to flush the buffer in a manner similar to std::cout. Further research led me to the [CPP Reference std::endl](#), which states, "In many implementations, standard output is line-buffered, and writing '\n' causes a flush anyway, unless std::ios::sync_with_stdio(false) was executed." This suggests that in many standard outputs, '\n' behaves the same as std::cout. Additionally, when I appended | cat to my program, I noticed that in file output, '\n' does not immediately flush the buffer.

In case you're looking at these slides Aolin, thank you for pointing this out!

A shoutout and clarification

However, upon testing these examples, I observed that '\n' seems to flush the buffer in a manner similar to std::cout. Further research led me to the [CPP Reference std::endl](#), which states, "In many implementations, standard output is line-buffered, and writing '\n' causes a flush anyway, unless `std::ios::sync_with_stdio(false)` was executed." This suggests that in many standard outputs, '\n' behaves the same as std::cout. Additionally, when I appended | cat to my program, I noticed that in file output, '\n' does not immediately flush the buffer.

In case you're looking at these slides Aolin, thank you for pointing this out!

A shoutout and clarification

```
int main()
{
    std::ios::sync_with_stdio(false)
    for (int i=1; i <= 5; ++i) {
        std::cout << i << '\n';
    }
    return 0;
}
```

You may get a massive performance boost from this. Read more about this [here](#)

In case you're looking at these slides Aolin, thank you for pointing this out!

**ASIDE: If you're interested in how
computers are able to do multiple things
at the same time take CS149!**

Use ‘\n’!

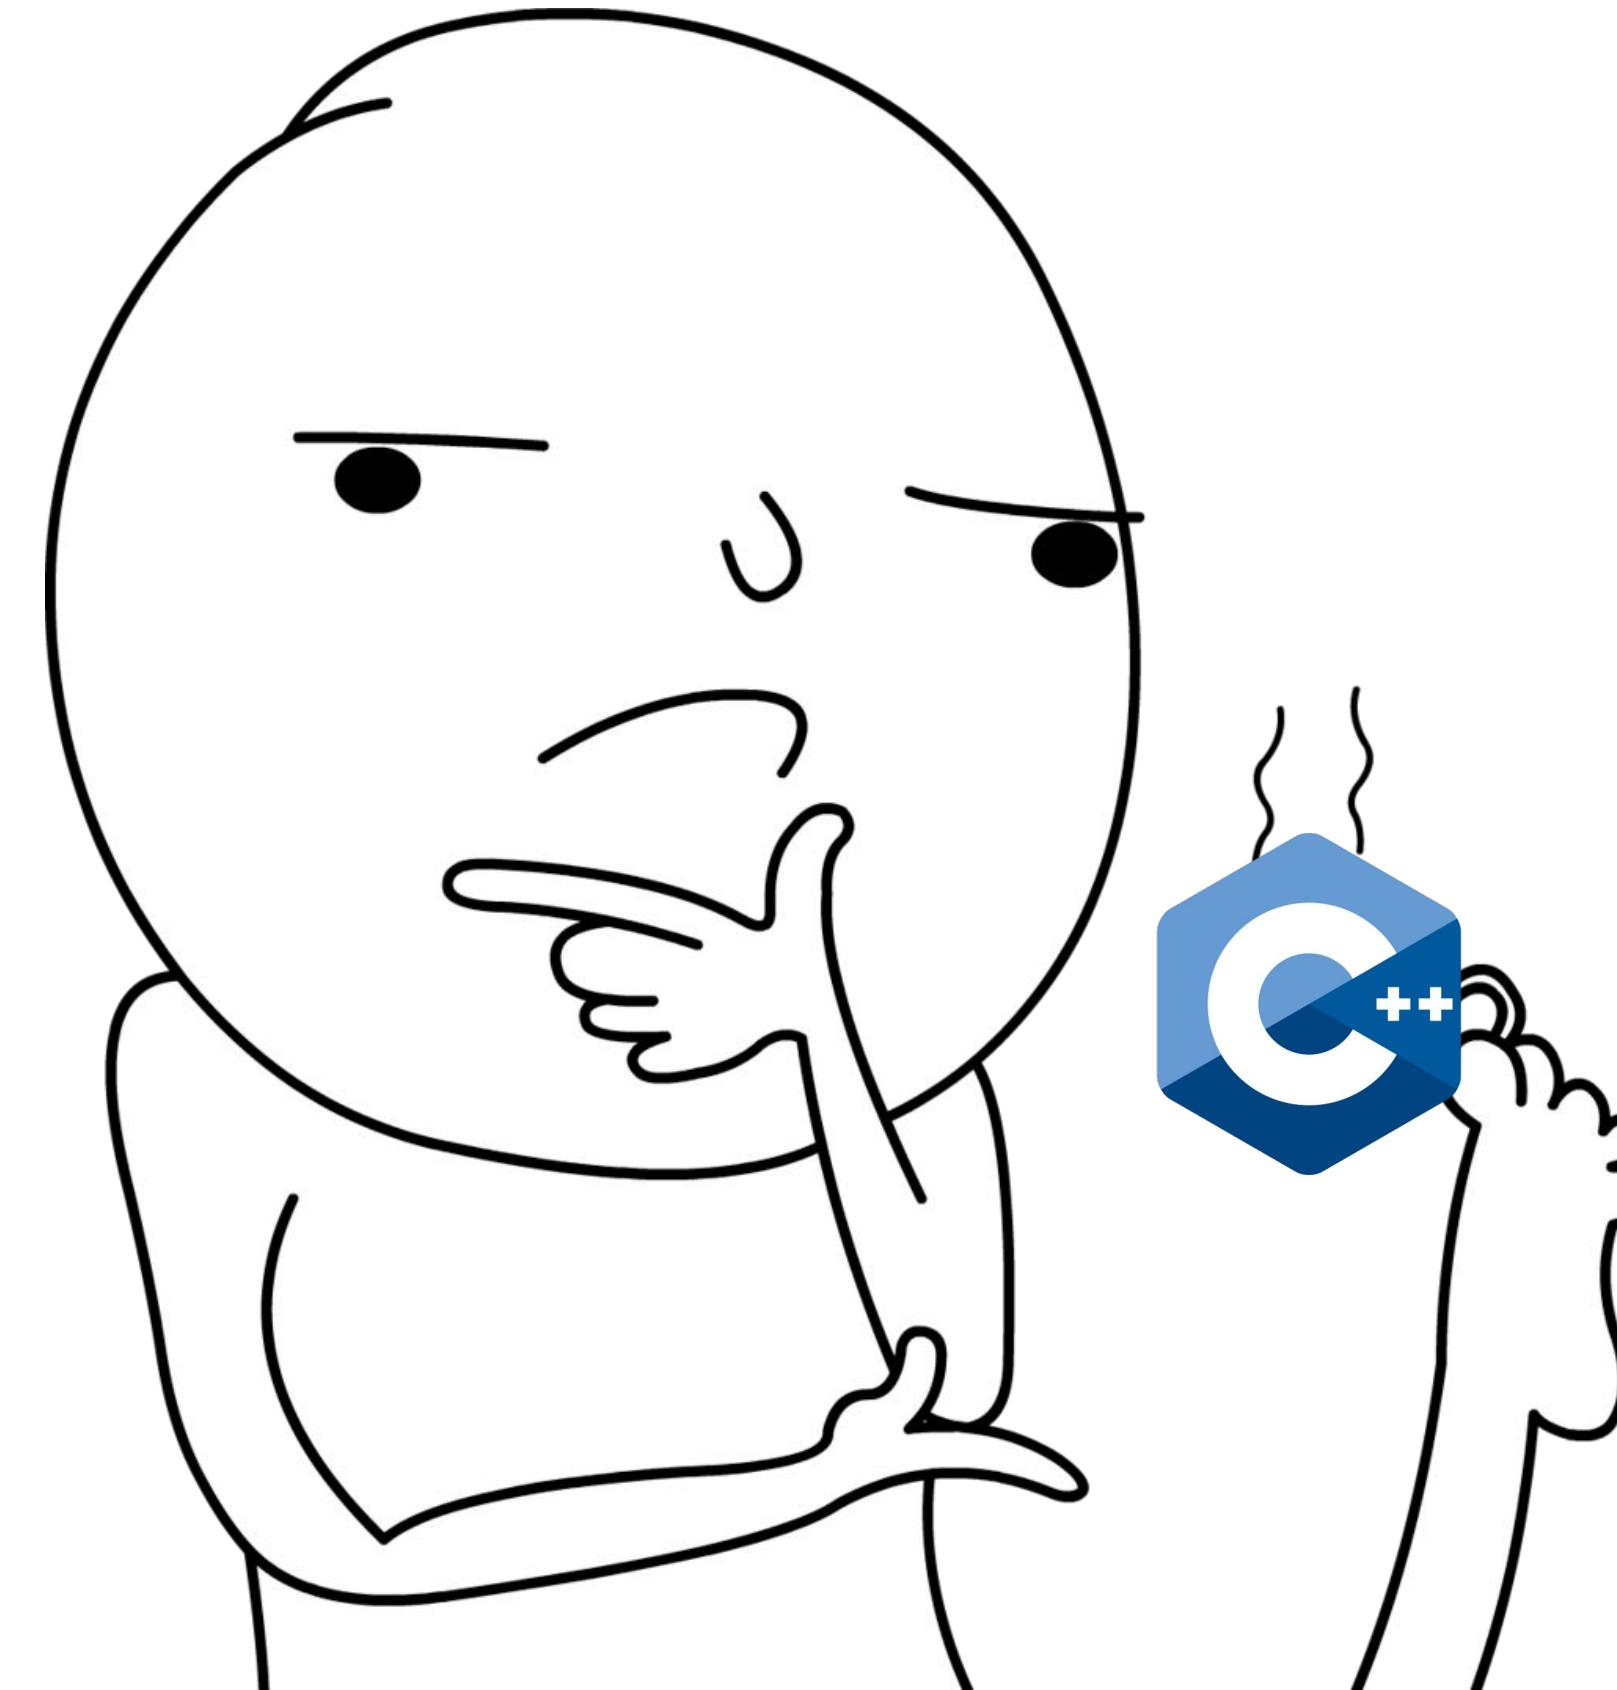

```
std::cout << "Draaaakkkeeeeeeee" << std::endl;
```

```
std::cout << "Draaaakkkeeeeeeee" << '\n';
```

What questions do we have?

Output File Streams

- Output file streams have a type: `std::ofstream`
- a way to write data to a file!
 - use the `<<` insertion operator to **send** to the file
 - There are some methods for `std::ofstream` **check them out**
 - Here are some you should know:
 - `is_open()`
 - `open()`
 - `close()`
 - `fail()`

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";

    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";

    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

Creates an output
file stream to the file
“hello.txt”

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";

    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

Checks if the file is open and if it is, then tries to write to it!

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";
    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

This closes the output file stream to "hello.txt"

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";
    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

Will silently fail

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";

    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

Reopens the stream

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt");
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";

    ofs.open("hello.txt");
    ofs << "this will though! It's open
again";
    return 0;
}
```

Successfully writes
to stream

Let's checkout some code!

My cue to see code :)

Output File Streams

```
int main() {
    // associating file on construction
    std::ofstream ofs("hello.txt")
    if (ofs.is_open()) {
        ofs << "Hello CS106L!" << '\n';
    }
    ofs.close();
    ofs << "this will not get written";

    ofs.open("hello.txt", std::ios::app);
    ofs << "this will though! It's open
again";
    return 0;
}
```

Flag specifies you want to
append, not truncate!

Input File Streams

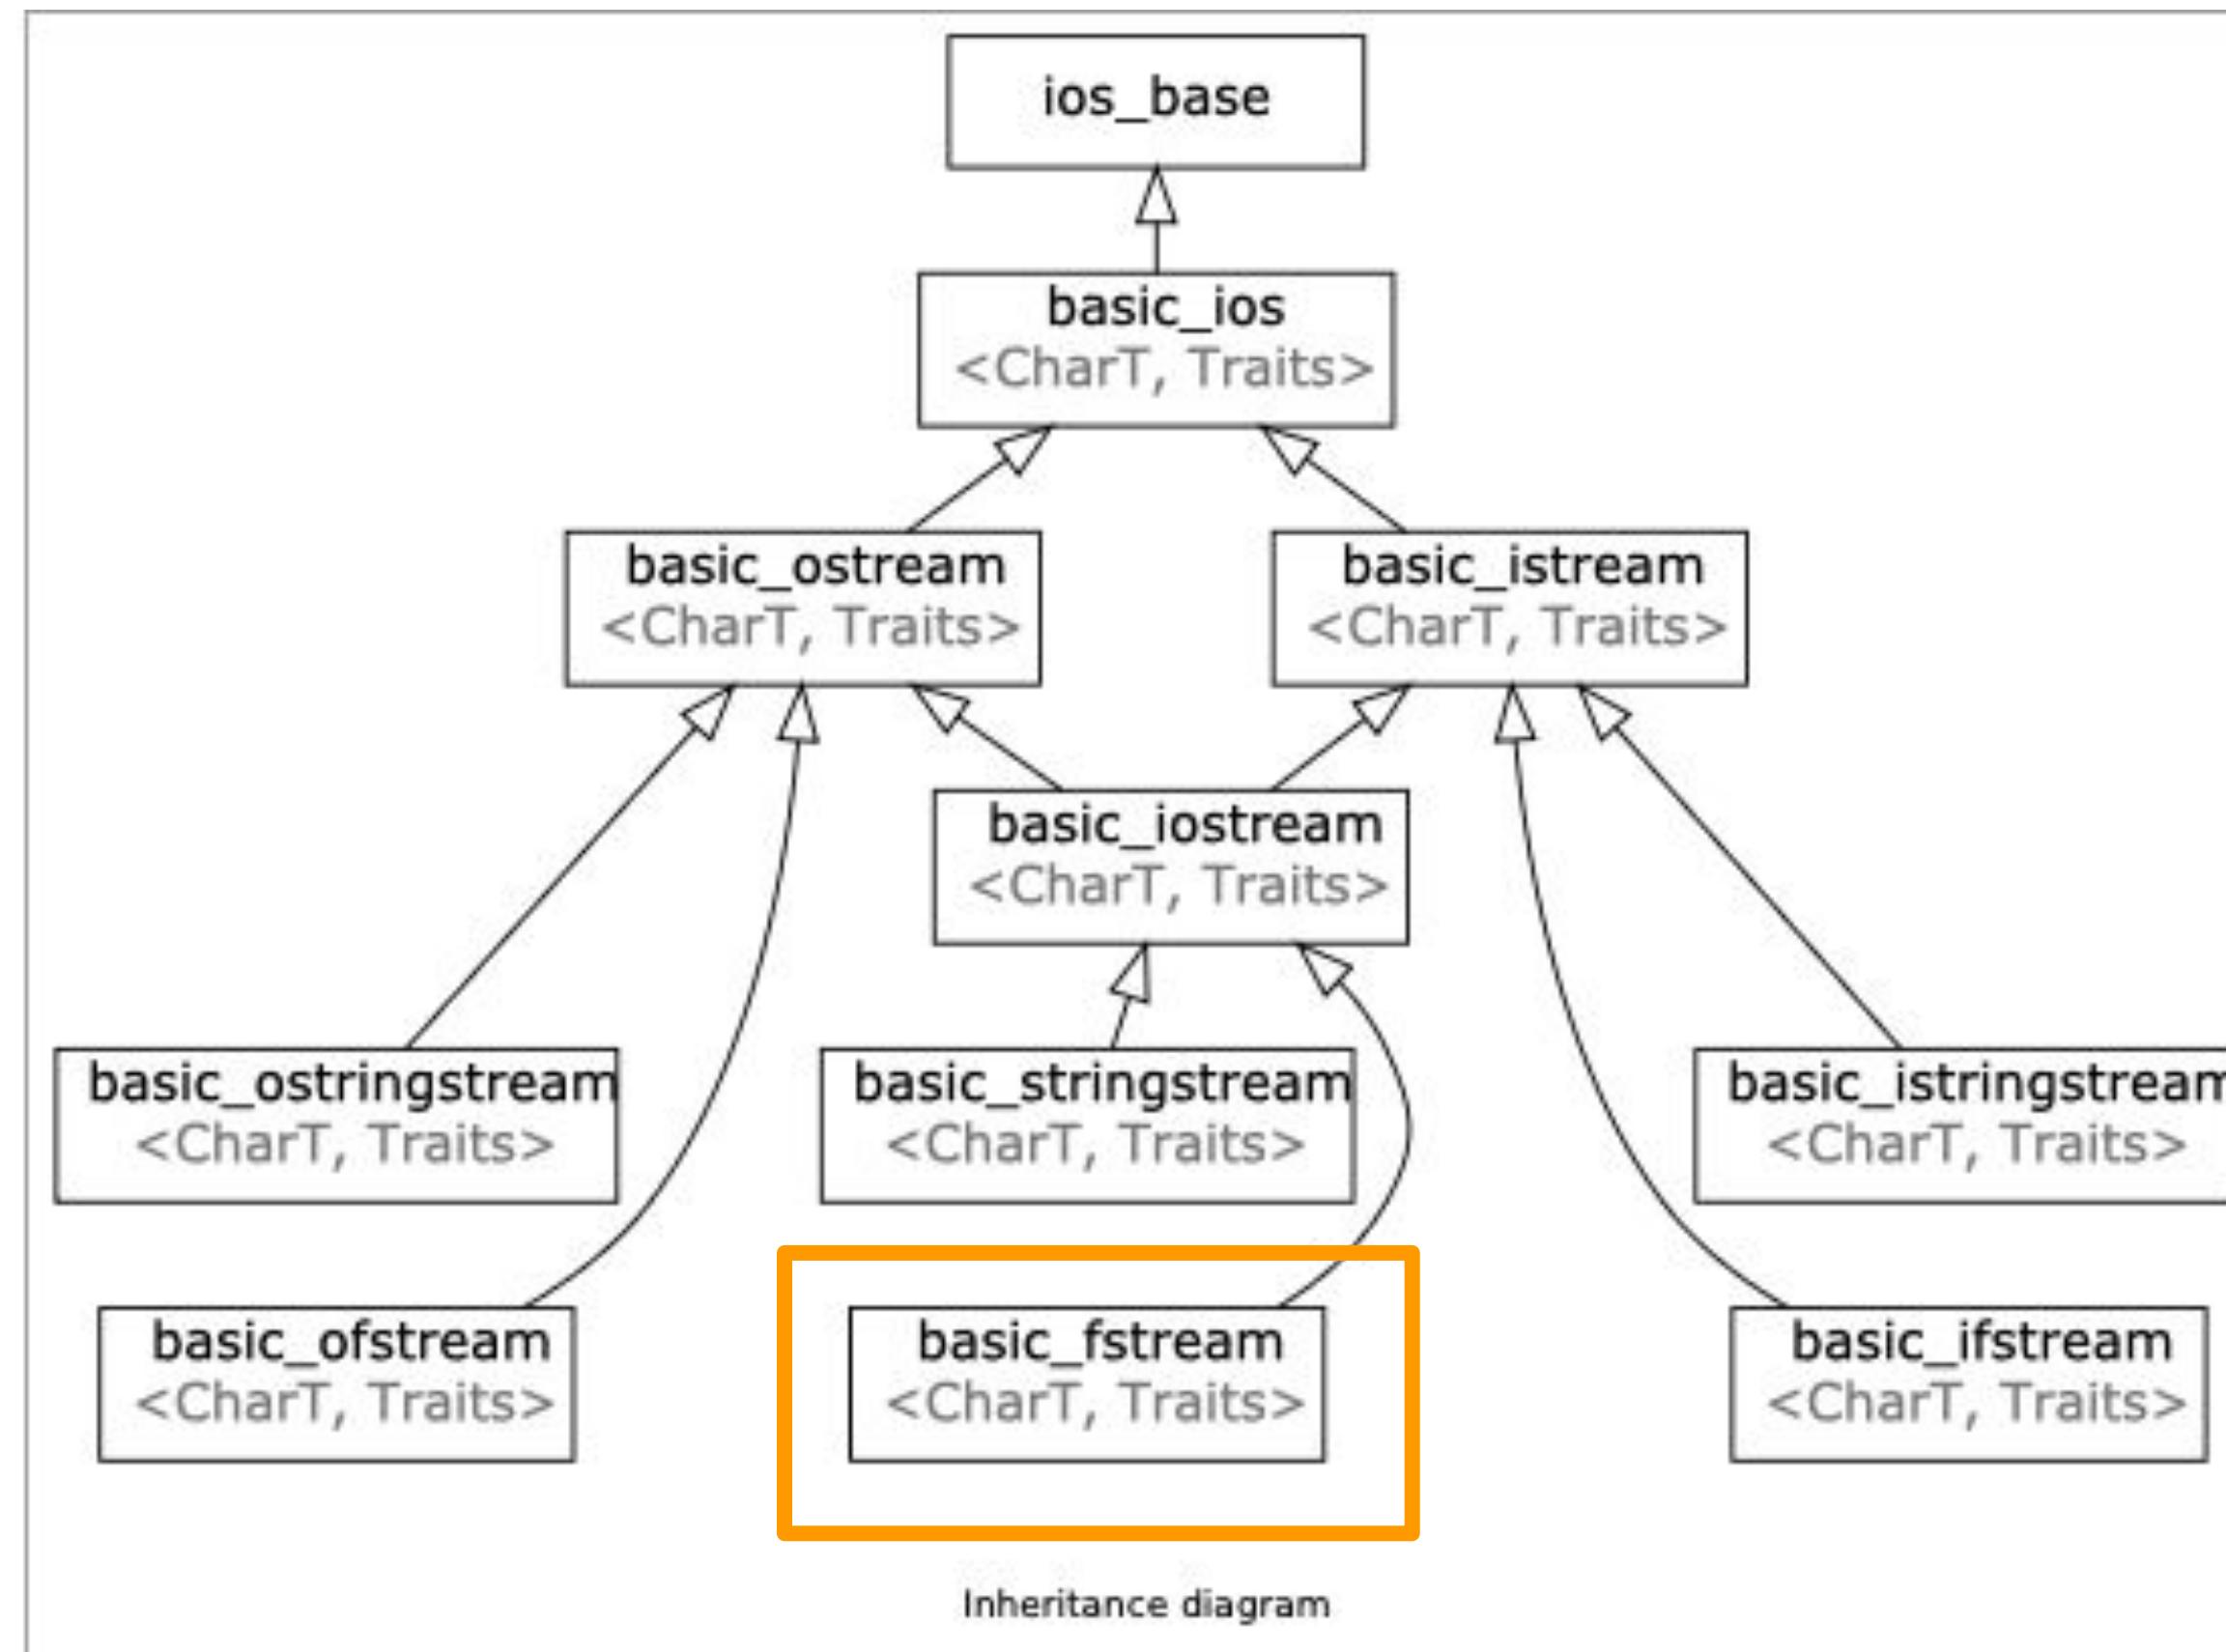

```
int inputStreamExample() {
    std::ifstream ifs("input.txt");
    if (ifs.is_open()) {
        std::string line;
        std::getline(ifs, line);
        std::cout << "Read from the file: " << line << '\n';
    }
    if (ifs.is_open()) {
        std::string lineTwo;
        std::getline(ifs, lineTwo);
        std::cout << "Read from the file: " << lineTwo << '\n';
    }
    return 0;
}
```

Input File Streams

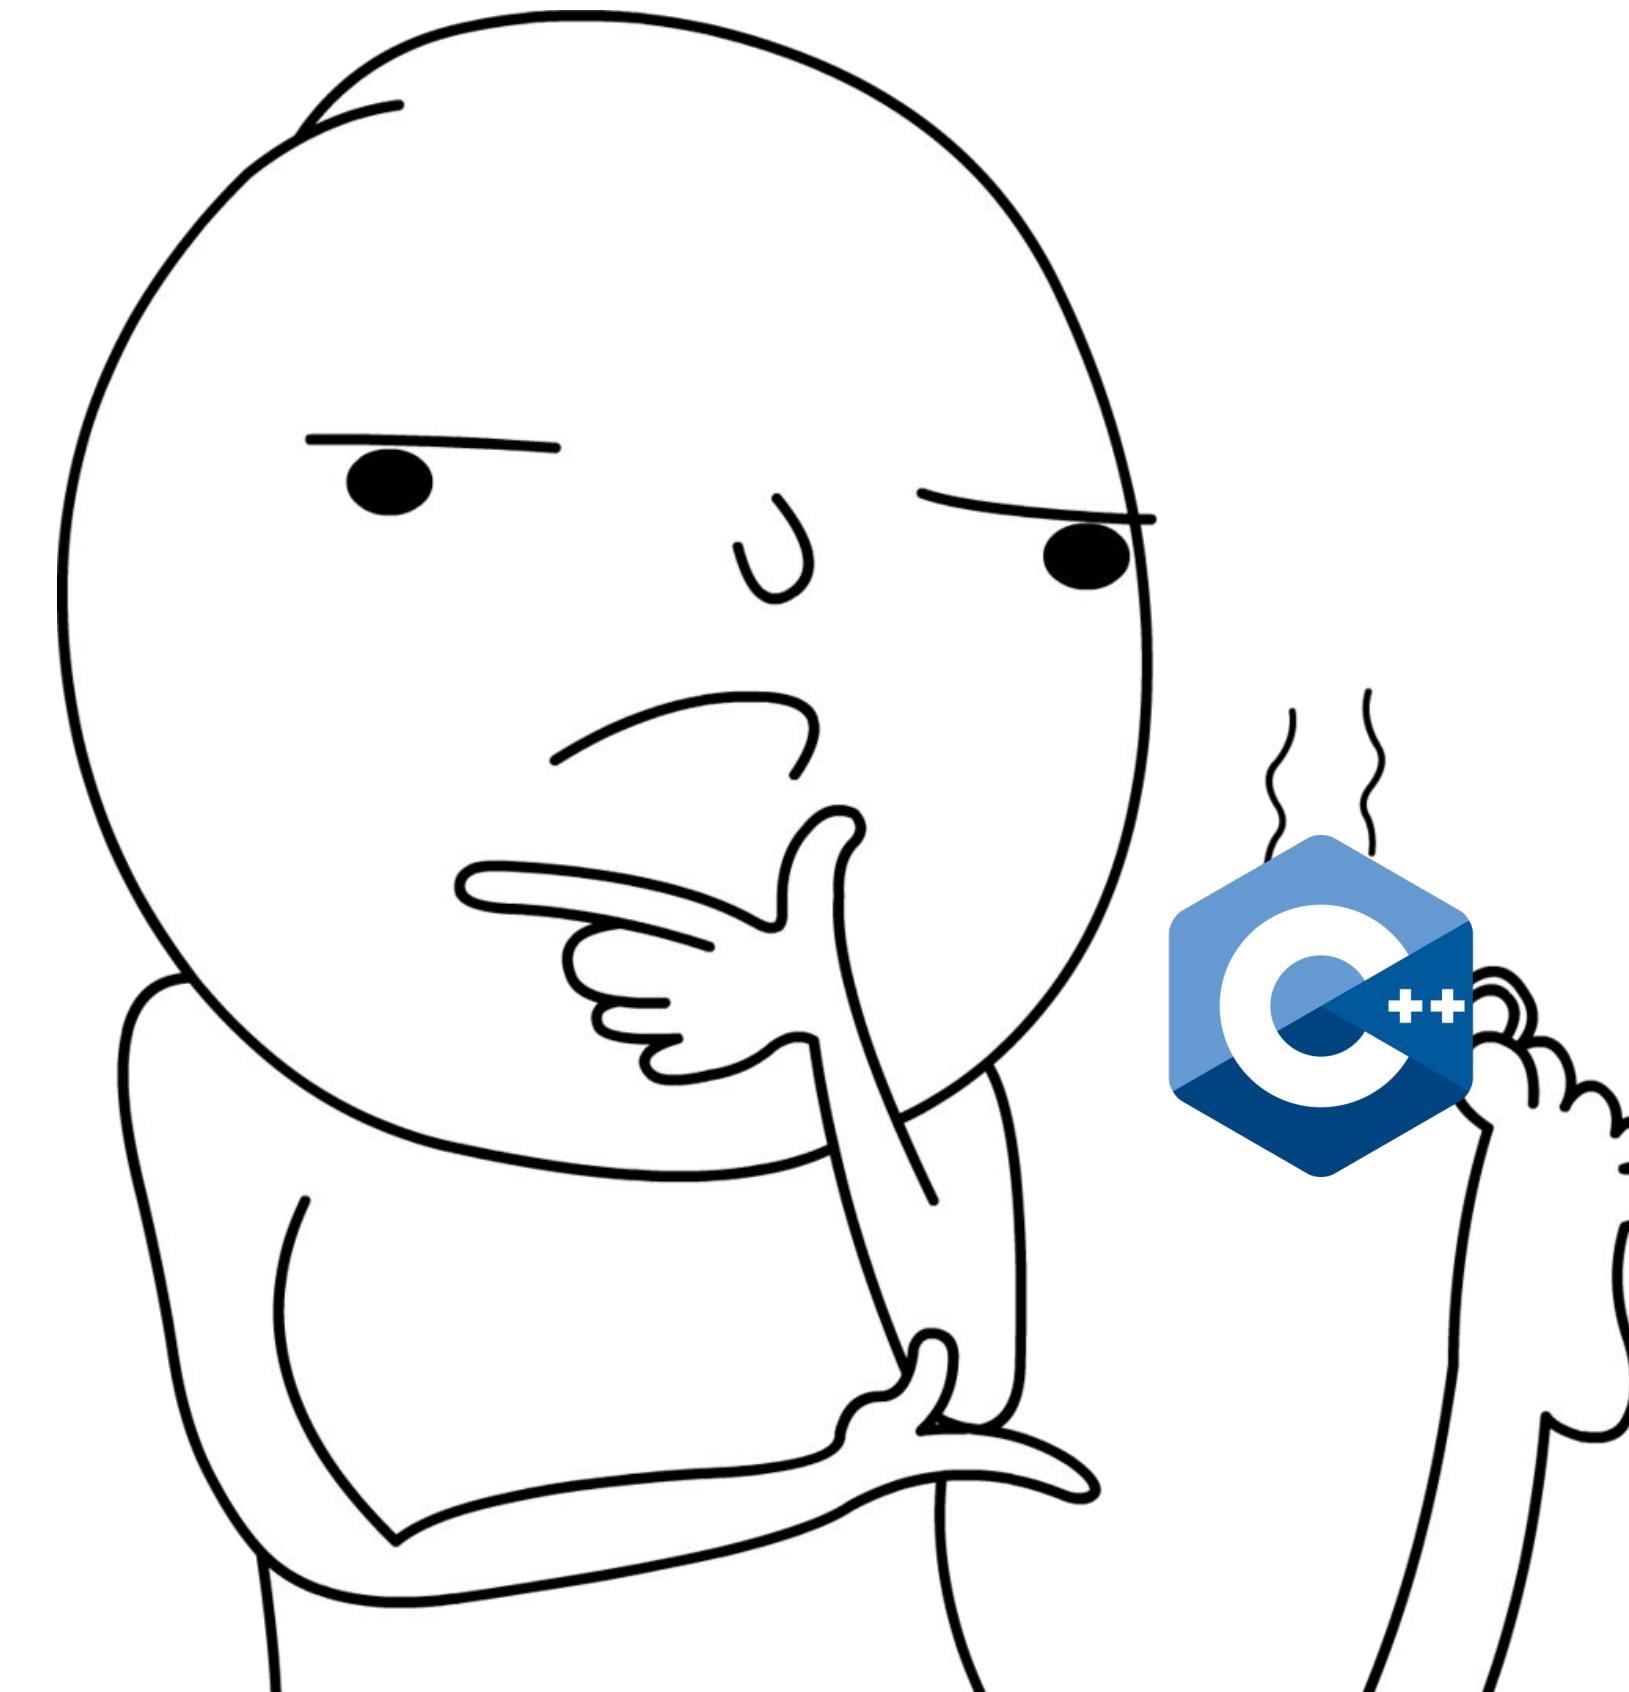

```
int inputStreamExample() {
    std::ifstream ifs("input.txt");
    if (ifs.is_open()) {
        std::string line;
        std::getline(ifs, line);
        std::cout << "Read from the file: " << line << '\n';
    }
    if (ifs.is_open()) {
        std::string lineTwo;
        std::getline(ifs, lineTwo);
        std::cout << "Read from the file: " << lineTwo << '\n';
    }
    return 0;
}
```

Input and output streams on the same source/destination type are complimentary!

IO File Streams

What questions do we have?

Plan

1. Quick recap
2. What are streams??!!
3. `stringstream`!
4. `cout` and `cin`
5. Output streams
- 6. Input streams**

Input Streams

- Input streams have the type `std::istream`
- a way to read data from an destination/external source
 - use the `>>` extractor operator to **read** from the input stream
 - Remember the `std::cin` is the console input stream

std::cin

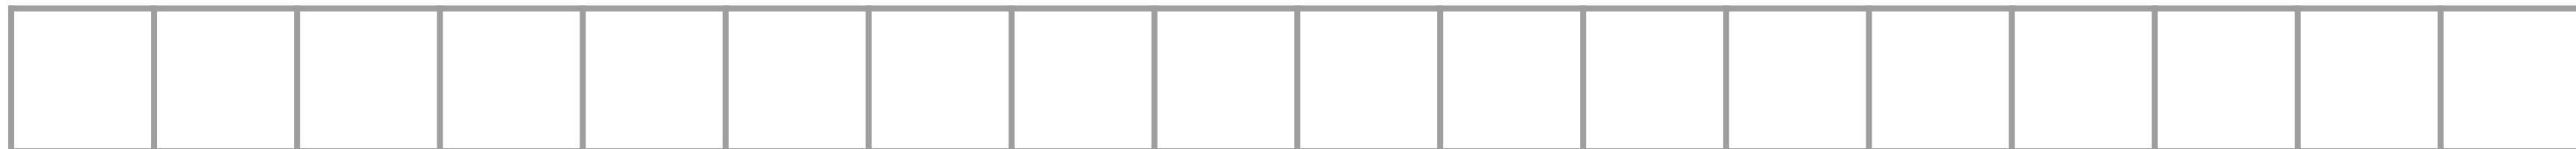

cin

- std::cin is buffered
- Think of it as a place where a user can store some data and then read from it
- std::cin buffer stops at a whitespace

std::cin

cin

- std::cin is buffered
- Think of it as a place where a user can store some data and then read from it
- std::cin buffer stops at a whitespace
- Whitespace in C++ includes:
 - “ ” – a literal space
 - \n character
 - \t character

std::cin

cin

```
int main()
{
    double pi;
    std::cin; // what does this do?
    std::cin >> pi;
    std::cout << "pi is: " << pi << '\n';
    return 0;
}
```

cin buffer is empty so
prompts for input!

std::cin

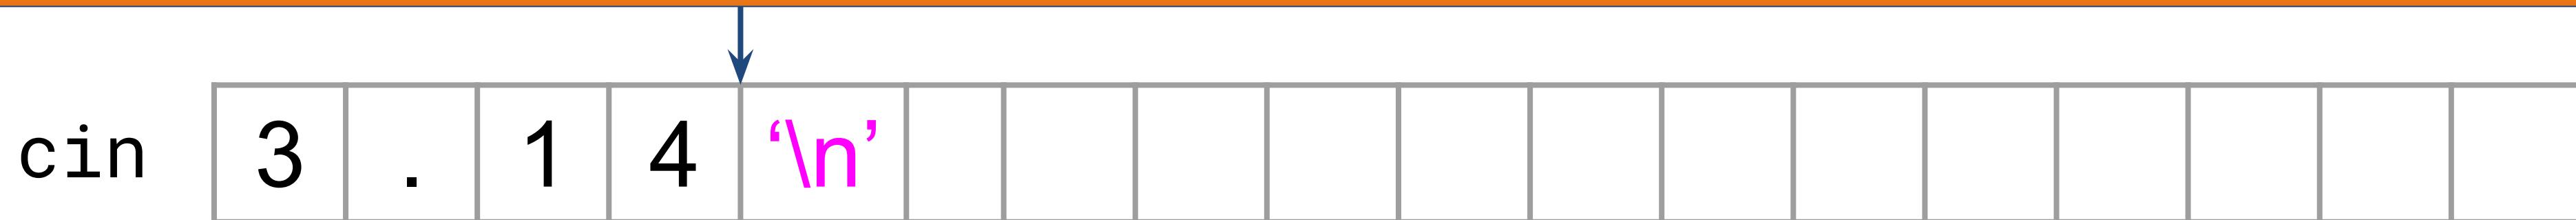

cin

```
int main()
{
    double pi;
    std::cin; // what does this do?
    std::cin >> pi;
    std::cout << "pi is: " << pi << '\n';
    return 0;
}
```

3.14

std::cin

```
int main()
{
    double pi;
    std::cin; // what does this do?
    std::cin >> pi;
    std::cout << "pi is: " << pi << '\n';
    return 0;
}
```

cin not empty so it reads up to white space and saves it to `double pi`

3.14

std::cin

```
int main()
{
    double pi;
    std::cin; // what does this do?
    std::cin >> pi;
    std::cout << "pi is: " << pi << '\n';
    return 0;
}
```

cout

“3.14”
“pi is: 3.14”

Alternatively

```
int main()
{
    double pi;
    std::cin >> pi; // input directly!
    std::cout << "pi is: " << pi << '\n';
    return 0;
}
```

“3.14”
“pi is: 3.14”

When std::cin fails!

cin

```
int main()
{
    double pi;
    double tao;
    std::string name;
    std::cin >> pi;
    std::cin >> name;
    std::cin >> tao;
    std::cout << "my name is: " << name <<
    " tao is: " << tao << " pi is: " << pi << '\n';
    return 0;
}
```

pi

name

tao

When std::cin fails!

```
int main()
{
    double pi;
    double tao;
    std::string name;
    std::cin >> pi;
    std::cin >> name;
    std::cin >> tao;
    std::cout << "my name is: " << name <<
    " tao is: " << tao << " pi is: " << pi << '\n';
    return 0;
}
```

cin prompts user to
enter a value saved in pi

3.14 pi
name
tao

When std::cin fails!

cin 3 . 1 4 \n F a b i o I b a n e z \n

```
int main()
{
    double pi;
    double tao;
    std::string name;
    std::cin >> pi;
    std::cin >> name; ←
    std::cin >> tao;
    std::cout << "my name is: " << name <<
    " tao is: " << tao << " pi is: " << pi << '\n';
    return 0;
}
```

cin prompts user to enter a value saved in **name**

3.14 pi

Fabio name

tao

When std::cin fails!

cin 3 . 1 4 \n F a b i o I b a n e z \n

```
int main()
{
    double pi;
    double tao;
    std::string name;
    std::cin >> pi;
    std::cin >> name; ←
    std::cin >> tao;
    std::cout << "my name is: " << name <<
    " tao is: " << tao << " pi is: " << pi << '\n';
    return 0;
}
```

Notice that `cin` **only** reads until the next whitespace

`cin` prompts user to enter a value saved in `name`

3.14

Fabio

pi

name

tao

When std::cin fails!

cin 3 . 1 4 \n F a b i o I b a n e z \n

```
int main()
{
    double pi;
    double tao;
    std::string name;
    std::cin >> pi;
    std::cin >> name;
    std::cin >> tao;
    std::cout << "my name is: " << name << " tao is: " << tao << " pi is: " << pi << '\n';
    return 0;
}
```

3.14 pi

Fabio name

?

cin buffer is not empty, so it reads until the next whitespace

When std::cin fails!

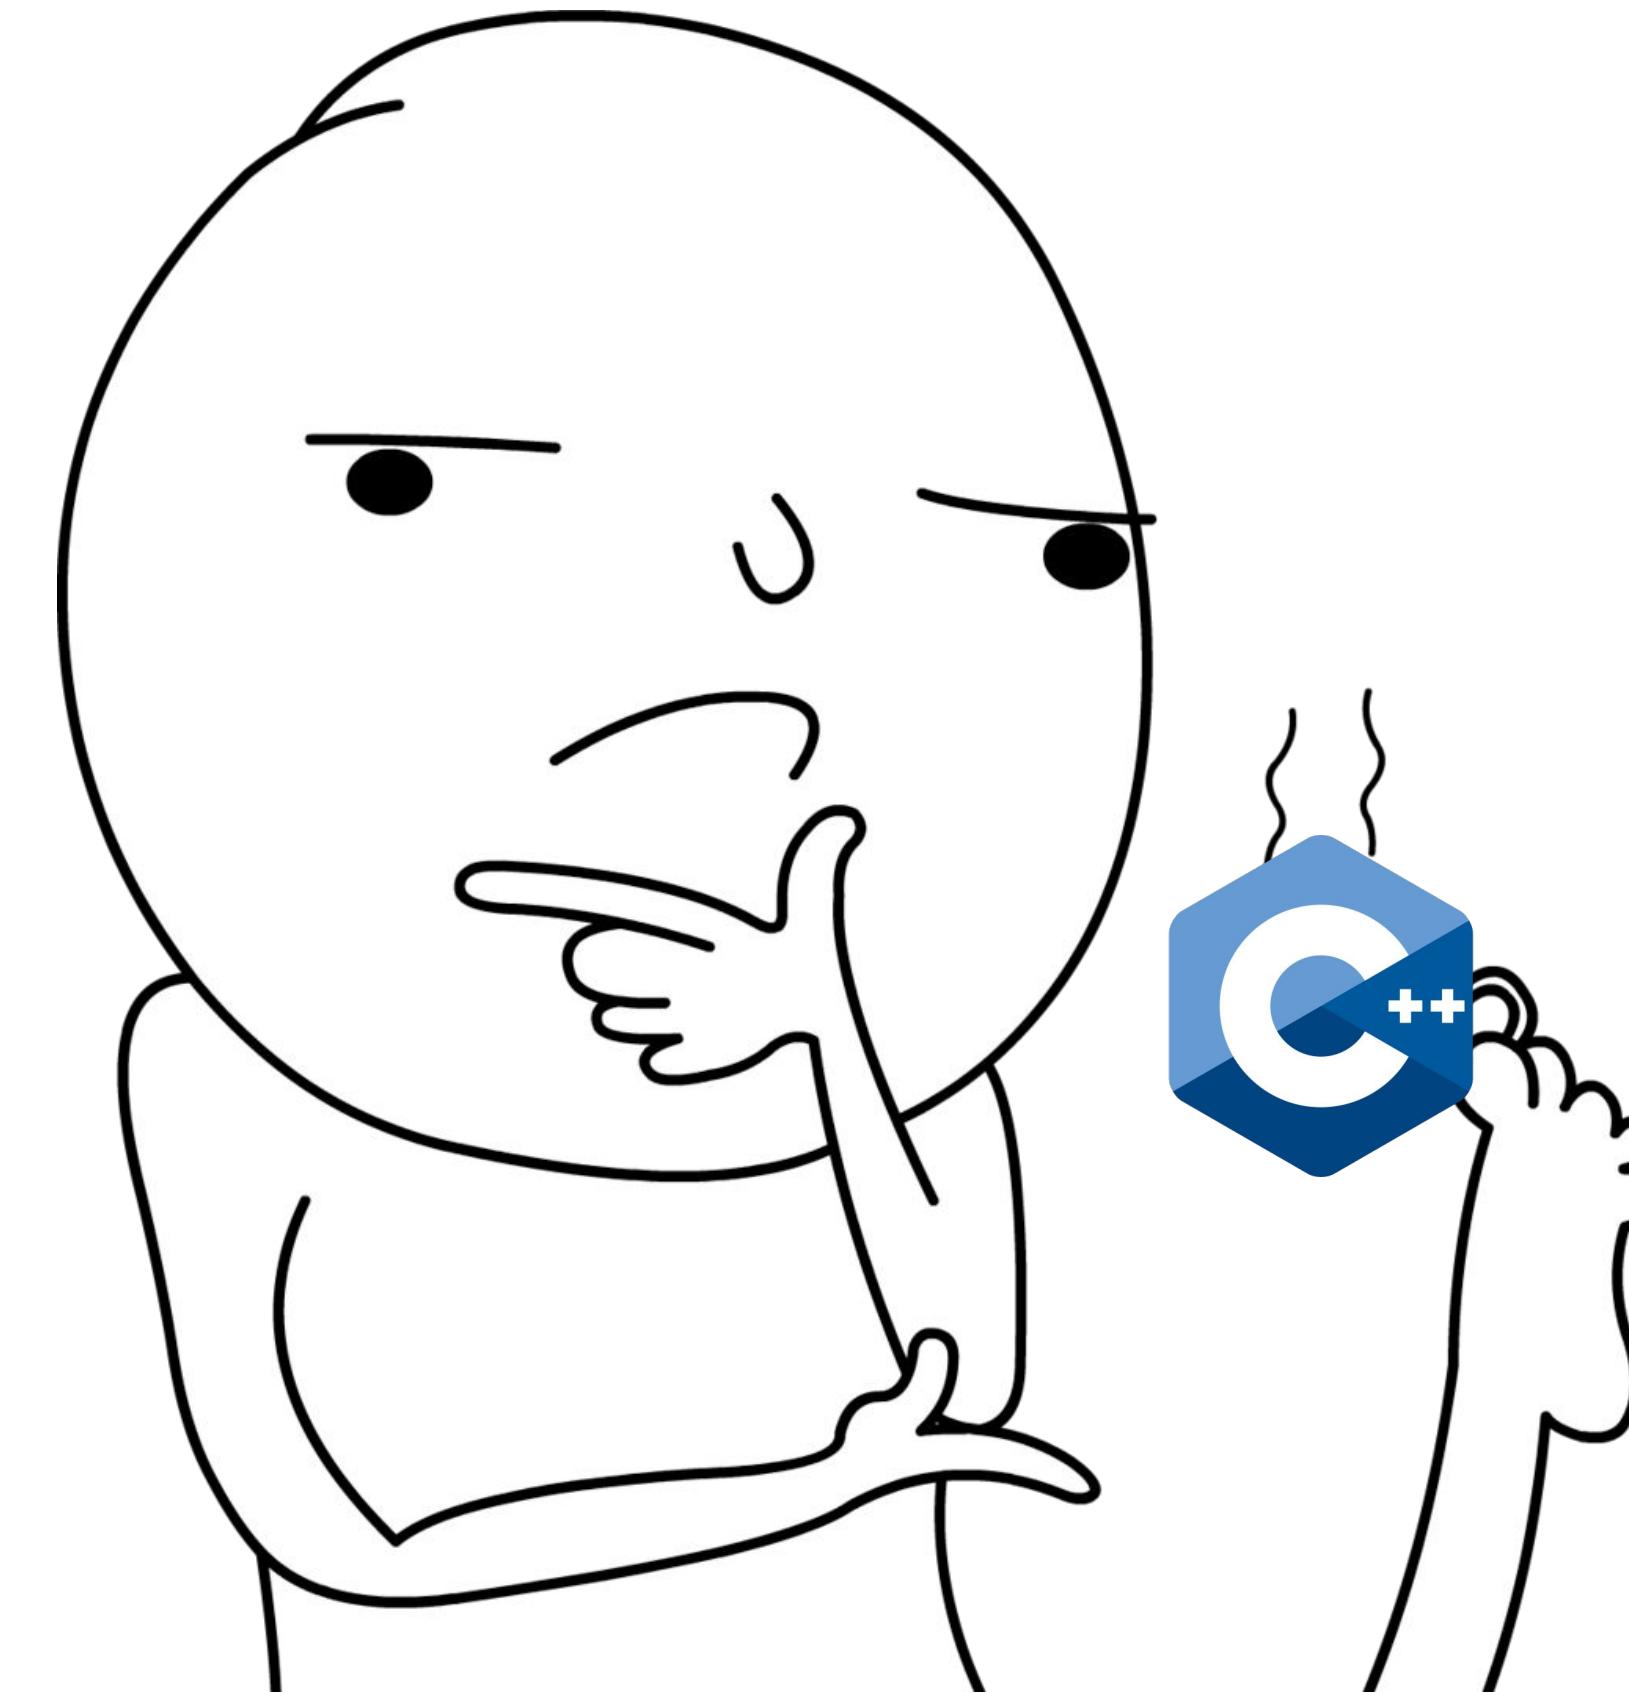

cin 3 . 1 4 \n F a b i o I b a n e z \n

```
void cinFailure() // replit name
{
    double pi;
    double tao;
    std::string name;
    std::cin >> pi;
    std::cin >> name;
    std::cin >> tao;
    std::cout << "my name is: "
    " tao is: " << tao << " pi is: " << pi << '\n';
}
```

cin buffer is not empty, so it
reads until the next whitespace

That being said

You shouldn't use **getline()** and **std::cin()** together because of the difference in how they parse data.

std::cin() - leaves the newline in the buffer
getline() - gets rid of the newline

Whew that was a lot!

To conclude (Main takeaways):

1. Streams are a general interface to read and write data in programs
2. Input and output streams on the same source/destination type compliment each other!
3. Don't use **getline()** and **std::cin()** together, unless you *really really* have to!

BYE, I'M OFF TO HOGWARTS

Acknowledgements

Credit to **Avery Wang's** [streams lecture](#) which I took a lot of inspiration from, particularly for formatting and flow.
